In the preface to his volume entitled *Aspects of Rheumatism and Gout, their Pathogeny, Prevention, and Control*, Dr. L. Jones Llewellyn apologizes for some overlapping, as the essays and addresses it contains were composed at various dates. In the opening chapter the history of the conception of diathesis is traced, and its recent revival approved, this prepares the way for the argument that the rheumatic diathesis is "an inborn predisposition to endocrine autonomic imbalance" and particularly connected with thyroid inadequacy, this opinion he supports by various considerations. The association of hyperthyroidism and Graves's disease with acute rheumatism is fully discussed, while believing that rheumatic fever probably develops on a hypothyroid basis, he assumes that there is a compensatory swelling of the thyroid, so that Graves's disease develops as an extension of acute rheumatism. Much consideration is given to the relation of goutic with the rheumatic diathesis, and thyroid instability or inadequacy is held to be important both in the uticular and non-uticular forms of chronic rheumatism. The relation of oral sepsis to arthritis is also considered in detail.

The author's work on gout was reviewed in these columns (1921, 1, 271), and in an address given at a later he returned to his conceptions of its etiological relations to focal infection, food idiosyncrasies, and protein hypersensitiveness. He suggests that gouty subjects, no hypersensitive not to alcohol, but to some protein contained in alcoholic beverages, such as horden in beer, or yeast or other proteins in wines, red wines being often tainted with white of egg. For this view that gout is an allergic disease support is sought in the writings of the French school of Chauffard and Vidal, the latter having shown by skin tests the peculiarly selective hypersensitiveness of the gouty to certain wines.

### AN AMERICAN TEXTBOOK OF GYNAECOLOGY

The well known treatise on the *Diseases of Women* by Harry Sturges Crossen, M.D., F.A.C.S., is a characteristic American production. It is bulky, very weighty, profusely illustrated, and encyclopaedic in its scope. The preparation of the new edition has not called for material alteration, save in the direction of bringing its matter generally up to date. The investigation of cases of sterility by a rays after the injection of opaque matter into the uterine cavity and tubal lumen for the diagnosis of tubal occlusions is one subject that has been fully revised. The general layout of its matter is as it was in the previous editions, though it cannot be described as scientific or logical. The arrangement is more on an anatomical than a pathological basis, but does not follow either. To give an idea of the author's scheme some of the chapter headings may be noted. The book opens with three chapters in which gynaecological examination, diagnosis, and treatment are discussed, next comes a chapter on diseases of the vulva and vagina, in which infections, growths, and regressive changes are dealt with. This begins from the external organs and working up to the ovary and peritoneal cavity. The next chapter, however, is one on relaxation and fistulae, then follow four nutritive disease, "displacement," and "growth," "inocent" and "malignant." There is a chapter on

*Aspects of Rheumatism and Gout, their Pathogeny, Prevention, and Control*. By Llewellyn Jones. W. B. Saunders Co., Philadelphia, 1927. (Demy 8vo 1 P. viii + 231.) 10s net.)  
*Diseases of Women*. By Harry Sturges Crossen, M.D., F.A.C.S. Sixth edition revised and enlarged. London: H. K. Lewis, 1927. (Sup. roy. 8vo, pp. xxvi + 1160. 933 figures. 50s net.)

pulvic inflammation in which the internal infective processes generally are treated, but such specific infections as tubercle are relegated to odd chapters. There is also a chapter on malformations, in which vulval, vaginal, and uterine developmental errors are described. This outline will suffice to indicate the total lack of orderly arrangement of its matter which is the chief fault in what is otherwise a sound presentation of gynaecological practice.

The clinical teaching is judicious and strikes a happy mean between the excesses of the extreme surgical enthusiast and the medical and minor procedures that were once supposed to characterize gynaecological practice. The use and place of the pessary is well discussed and the sections on the internal secretory glands and their relation to gynaecology give a well balanced view of our present knowledge. There are a few pages on the neurological side of gynaecological practice but this aspect is scarcely considered in some sections of the book where it might have been expected to be discussed. For instance, in conditions such as vaginismus and dyspareunia in which the psychoneurotic element is clearly predominant no reference is made to the psychological factor.

The illustrations are excellent particularly those of pathological specimens and histological slides; this sixth edition is sure to meet with as hearty a welcome as its predecessors.

### VICIOUS CIRCLES

As most of our readers are aware, Dr Jamieson B. Hurry, formerly of Reading, has written several books on vicious circles in disease. Now we have from Dr Lorenzo Pezzotti an Italian criticism of the conception of vicious circles in pathology. Dr Hurry describes a large number of circles and discusses how they may be broken; the Italian author seems to think that the method has been rather overdone inasmuch as an impression has been created that there is such a thing as circular pathology, although Dr Hurry warns his readers against any such one-sided view. One of the instances cited is stone in the bladder; the stone gives rise to cystitis, the cystitis causes further increase in the size of the stone; this intensifies the existing cystitis and so on. The inference to be drawn is that a vicious circle has been established which needs breaking, and that this is best effected by removal of the stone. This seems an unnecessarily roundabout way of arriving at the fact that the patient wants to get rid of his stone. There are cases however in which the notion of a vicious circle is useful and Dr Pezzotti admits this; he contends on the other hand that generally speaking, it is unscientific and undesirable to regard disease from the point of view of vicious circles.

Dr Pezzotti maintains that the circles are in fact not vicious, but depend on normal physiological arrangements; that the vicious element is merely a defect in one of the organs concerned in the circle or altogether outside it and that in concentrating attention on the circle important factors are apt to be overlooked. Thus to take another example of Hurry's, that of nephritis, a toxæmia damages the renal epithelium; this causes an increase in the toxæmia which in its turn further damages the renal epithelium and so on. The danger here is to lose sight of the fact that the circle depends on an outside factor, namely the cause of the initial toxæmia; the whole disease depends on this factor and the vicious circle can be interrupted only by its removal. To leave it out of account would Dr Pezzotti considers be analogous to regarding the swing of a pendulum to the right as the cause of its swing to the left and vice versa without reference to the spring or weights. It must be admitted however that where the primary cause of a disease is inaccessible it may still be possible to make some beneficial modification short of complete interruption in a vicious circle; palliative treatment is often of this nature and the notion of the vicious circle serves a useful purpose in such cases.

### TREATMENT OF CANCER BY INJECTIONS OF METALLIC SALTS

Just May Dr J. LERICHE of Joigny read a paper to the French Society of Therapeutics on "the medical treatment of carcinoma," this has now been published in a pamphlet,\* together with another article by him on the association of the endocrine glands with cancer, in which he suggests that the "specific factor" postulated by Gre and Barnard has its origin in endocrine disturbance. Leriche holds that the neoplasm and its metastases can be attacked by the injection of colloid metal salts but that it is also necessary to correct certain mineral and other deficiencies in the body. For the first purpose he employs a mixture of the colloid preparations of copper, selenium, palladium, magnesium and arsenic sulphide with mesothorium bromide and strontium. He states that intramuscular injections of this medley are not painful and are always well tolerated. He administers concurrently intravenous injections of a combination of the citrates of sodium, magnesium, and manganese, magnesium chloride and ferric potassium tartrate. If benefit does not follow speedily he gives intravenous or intramuscular injections of a protein suspension of lead. With a view to dealing with the alleged mineral deficiency in the tissues, Leriche also administers three preparations: the first containing crystallized haemoglobin, manganese sulphate and ferrous oxalate; the second colloidal sulphur and the third a mixture of magnesium carbonate, yeast, lactose and calcium carbonate. If these are not well tolerated an aqueous solution or the double peptonate of iron and manganese is substituted. Organic deficiencies are treated by the administration of glandular extracts, the mixture containing the fresh pituitary and thyroid glands of sheep or suprarenal and according to the sex, either ram's testis or heifer's ovary; this polyglandular medication is varied according to the seat of the cancer. In mammary carcinoma for instance it should include extracts of thyroid, pancreas and mammary gland while in elderly patients genital gland extracts should constitute the greater part of the medication. Chemical details of six patients so treated are given with illustrative radiograms. His cases were a large pleuric neoplasm, an inoperable tumour of the chilo-pelvic colon, an inoperable gastric neoplasm, and another of the descending colon, an inoperable carcinoma of the right thigh and a similarly situated osteosarcoma. These patients had received other treatment previously (surgical, x-ray or radium) without definite benefit. In each case apparent cure without recurrence is stated to have followed the injection treatment. It is to be noted that the diagnosis was based only on the clinical symptoms and radiograms, no confirmatory histological examination being made. In this awe-inspiring galaxy of medicaments there is a reminiscence of the elaborate prescriptions of a bygone age. It is easy to understand that a certain amount of scepticism has resulted but it is apparent that the age of brighter therapeutics is still with us.

### IDIOSYNCRASY AND CONSTITUTION

SIR HUMPHRY ROLLESTON has written a book on *Idiosyncrasies*† which small as it is seems to touch upon every aspect of that perplexing subject. It is a contribution to a series of little books called "Psyche Miniatures" because published in connexion with *Psyche*, a quarterly journal on psychology. The series is edited by Mr C. K. Ogden who seems to possess a broad-minded mental perspective and chooses his writers wisely. In the course of his essay Sir Humphry Rolleston has to deal with the subjects of diathesis and the constitutional factor in disease recently discussed with so much acumen in our columns by Sir Archibald Garrod and Dr A. F. Hurry. It is difficult to define idiosyncrasy. Sir Humphry Rolleston speaks of it as an abnormal reaction in an otherwise normal

# NOTES ON BOOKS

person, which may be either on the one hand greatly exaggerated, or on the other hand greatly diminished, more briefly it may be described as an unusual physiological personification of "Idiosyncrasy" may be held to embrace both diathesis and constitution, but the author of this informing book would limit diathesis to a condition favouring the onset of disease, whereas idiosyncrasy is an abnormal reaction not necessarily disposing to disease. Within the definition of "constitution" he would bring the inborn errors of metabolism, so named by Sir Archibald Garrod, we are inclined to think that he is right, and even disposed to suggest that he has not quite attached sufficient importance to these inborn conditions.

One section of the book deals with asthma, it contains a comprehensive survey beginning with Sir John Floyer (1649-1734), and coming down to the latest views of Hirst and Storm van Leeuwen. The same subject is dealt with in Hirst's own contribution to the series entitled *The Constitutional Factor in Disease*, which is a revision of the address published in our columns in May, 1927. He, it may be remembered, lays stress on the influence of heredity, and it is perhaps on this account that he defines asthma as "a condition in which that part of the vagal nucleus which controls the motor and secretory activity of the bronchi is abnormally sensitive to chemical, reflex, and psychical stimuli."

## NOTES ON BOOKS

*Mental Handicaps in Art*, by Dr. T. B. Hyslop, the author also of *Mental Handicaps in Art*, which is reviewed in our issue of June 4th, 1927 (p. 1025), is introduced by a foreword from Professor Arthur Thomson of Oxford, who, with the authority of a professor also at the Royal Academy of Arts, sternly rebukes the modern fashions of perverted art, and about a tendency to degeneracy in present day art, remarking that one of the great mental handicaps in some schools of art is a failure to perceive the illogical nature of then tenets, and that since the evolution of taste in art has proceeded agreeably, impressionists, post impressionists, and decadents having contributed respectively either to its growth or decay. The five chapters of this attractive little volume deal with the aims and objects of art, industry and art, the artistic faculty, disease, and the influences of toxins on mind and body. Dr. Hyslop, who by his artistic abilities is specially fitted to write on these subjects, points out that while normal functional powers are essential for a healthy artistic faculty, abnormality may lead to something out of the beaten track or a work of degeneracy—in fact, the artistic merit of a painter may be great. But he concludes by insisting on the importance of mental and physical health, so that *mens sana in corpore sano* should be the motto of every artist.

*Common Procedures in the Practice of Pediatrics* by Dr. May Brown and Dr. F. F. Isidore, includes a curious assortment of subjects and its contents are indicated by the subtitle—a detailed description of diagnostic, therapeutic, and dutet methods employed at the Hospital for Sick Children, Toronto. There is a short account of physical examination and two chapters on the diet and general control of infants and young children, which, although not complete, deal with the more important matters both in then general principles and in then practical details, the remaining chapters are devoted to the exposition of a long series of diagnostic and therapeutic procedures both chemical and laboratory. A useful section on the diagnosis of certain conditions that frequently give difficulty is interspolated. The authors themselves make it clear that the book is not a complete account of the comprehensive subject of pediatrics. But it is a very useful book for it is written from experience, and it deals with a miscellaneous group of subjects which are either omitted or dealt with inadequately in the ordinary textbooks.

*Mental Handicaps in Art*. By Theo F. Hyslop. M.D. C.M. etc. With a foreword by Arthur Thomson. M.B. F.R.C.S. L.D. D.C.L. Mental Handicap Series. London: Baillière Tindall and Co. 1927. (Fcap 8vo, pp. xviii + 98. 3s. 6d. net.)

*Common Procedures in the Practice of Pediatrics*. By May Brown and Frederick F. Isidore. M.D. F.R.C.S. L.R.C.P. London: Baillière Tindall and Co. 1927. (Med 8vo, pp. x + 250. 4 dollars.)

The third quarterly number of this year's *Annals of Medical History* begins with an oration delivered at the College of Physicians of Philadelphia by Dr. Astley Paston Cooper, an Ashmun on "The centenary of Lister's tale of sepsis and antiseptics," which is accompanied by the pleasing portrait of Lister is President of the Royal Society and for many years its emperor, shown by Dr. W. S. Middleton and for many years its much in advance of his time, for he made many attempts to fly, was an early microscopist, and made experiments on telephony. Dr. A. H. Brinkley tells us that Dr. Joseph Buchanan (1785-1829) was an inventor as well as a medical man, he designed an economical steam engine with spiral capillary tubes, and he also attempted to construct a ship. On the cover of this number is the portrait of Alexander Monro secundus, who, with his father and son, is discussed by Dr. S. William Simon, then tenures as professors of anatomy at Edinburgh covered the period 1719 to 1859. The second Monro, the ablest of the three, among other notable achievements invented the original stomach pump. His son was robust, and it is stated that his editing of his father's essay and heads of lectures detracted considerably from their value. Dr. O. L. Denney of the U.S. Marine Hospital No. 66 (National Leprosarium) contributes an "Inaugurate medical debate on Elephantiasis on Leprosarium," translated by Chiplum Binchut Shetter from the original Latin and Greek of Benjamin Niesius, who defended this thesis in July 1673 at Strasbourg. It closes with a eulogy to William Niesius also a physician, coming. In the twenty-first instalment of pre-epithological studies Dr. Roy L. Moodie, in a generous illustration which occupies thirty pages, describes the head injuries among the operations.

A second edition has appeared of Dr. D. C. Munro's book on *Pulmonary Tuberculosis, its Etiology and Treatment*, which was reviewed the first on October 28th 1922 (p. 805). In the new volume the original scheme and the philosophic outlook are retained. Although in many respects the orthodox outlook as regards etiology is rejected, yet the author's experience in treatment and his skill in setting out his case render it a provocative book well worthy of study. It is only to be regretted that too many of the recommendations for after care involve a return to a less useful form of life than is at present possible for the majority of tuberculous patients who are forced by financial considerations to live in crowded communities.

Smith's Medical Visiting Lists for 1928 (Nos. 3 and 4) are handy little volumes, with ruled pages for visits, for obstetric and vaccination engagements, addresses of patients and nurses, and cash memoranda. The visiting list (No. 3) has space for seventy-five patients each week, with a weekly journal attached. It costs 7s. 6d., and can be obtained from Messrs. Hazzell, Watson and Viney, printers and binders, 160, Shaftesbury Avenue, W.C.2.

*Annals of Medical History*. Vol. 15, No. 3. Edited by Francis R. Packard. M.D. New York: Paul B. Hoeber, Inc. London: Baillière Tindall and Co. 1927. (8 1/2 x 12 1/2 pp. 265-314. Illustrated. Subscriptions in Great Britain £2 2s. for volume of four numbers.)

*Pulmonary Tuberculosis, its Etiology and Treatment*. By David C. Munro. M.D. W.R.C.S. L.R.C.P. Second edition enlarged. London: Baillière Tindall and Co. 1927. (Demy 8vo pp. cxxi + 81. 8s. net.)

*Smith's Physicians and Surgeons Visiting List, Diary, Memoranda and Book of Engagement for 1928*. Eighth second year. London: Hazzell, Watson and Viney Ltd. (No. 3 cloth 7s. 6d. leather 10s. 6d. No. 4, cloth 10s. leather 12s.)

## PREPARATIONS AND APPLIANCES

**METALIX X-RAY TUBE**

One of the notable pieces of apparatus shown at the recent exhibition in connection with the inaugural meetings of the Royal Society and the British Institute of Radiology was the Metalix X-ray tube introduced by Philips' Lamps Limited of Charing Cross Road, London. There have been many changes in X-ray tube construction since the first models—wooden looking affairs now as seen in the collection at South Kensington—first years ago but each tube has obviously evolved from its predecessor, whereas the Metalix tube is such a radical departure that it is partly because of its extremely small size and non-bulbous shape, and also because the rays are generated within a metal cylinder working conditions but two types warrant special attention. The Philips 'Metalix' tube is constructed with a metal cylinder of other a special tube for deep therapy. In the radiography tube it is claimed by the makers that the high load which in the past is made to stand is not at the expense of fine focus and that which are well known. It is claimed for all these tubes that they embody their own protection.

## RADIUM THERAPY

## REPORTS FROM RESEARCH CENTRES

THE Medical Research Council, which is entrusted by the Government with a stock of radium salt for distribution, has issued a summary of the reports on the medical uses of this element received from centres for the year 1926. Radium was supplied to nine clinical centres—namely, the Middlesex Hospital, University College Hospital, St Bartholomew's Hospital, King's College Hospital, the London Hospital, St Peter's Hospital, Birmingham General Hospital, Cardiff Royal Infirmary, and Aberdeen Royal Infirmary. In addition to this the London Association of the Medical Women's Federation receives radium for use in a group of hospitals, and radium salt is also allocated to the Irish Radium Committee in Dublin for distribution in Ireland. In an introductory note to this report of the Council it is stated that during the last five years it has become clear that these centres have followed three main lines of radium treatment—namely, a combination of surgical measures with radium, the introduction of this element into the tissues, and its superficial application. Reports for the year under review have been published elsewhere in *extension* from University College Hospital, the London Association of the Medical Women's Federation, and the Irish Radium Committee.

## Clinical Investigations

The investigations considered in the report are classified as in previous years, under six headings—namely cancer of the breast, cancer of the cervix, carcinoma of the mouth, nasopharynx, larynx and oesophagus, carcinoma of the rectum and bladder, sarcoma and lymphosarcoma, and experimental investigations.

Cancer of the breast was treated by surgical radium therapy at the Middlesex and St Bartholomew's Hospitals, the radiological methods being appreciably different in the two cases, though the aim from the surgical point of view was the same. The employment of comparatively large quantities of radium acting for about twenty-four hours was the method adopted at the Middlesex Hospital while at St Bartholomew's Hospital a number of distributed foci containing small quantities of radium were allowed to act for about a week. By continuing such comparisons for a few years it is hoped that a decision will be reached as to which technique is the more advantageous. The Middlesex Hospital report describes the radium treatment of thirteen cases of recurrent carcinoma of the breast, eleven being radical operations and two being local, or incomplete operations. In three cases recurrences disappeared finally, in seven they disappeared but returned locally or elsewhere, and in three there was little or no improvement. The results of treatment of seven patients with recurrent carcinoma of the breast are also given in four recurrences disappeared and did not return, in one case the growth was excised before treatment and there was no recurrence, in two cases there was little or no improvement. Five primary growths were treated similarly, in four cases they disappeared without recurrence and in one case there was great improvement. Surface radium therapy was tried at the Middlesex Hospital in seven cases of primary carcinoma of the breast with considerable benefit in most cases. It was also used in twenty cases of inoperable supraclavicular recurrences, and in thirty-three cases of nodular recurrences. Ten cases of recurrent carcinoma with cutaneous nodules were treated with radium in conjunction with x-rays at King's College Hospital; the nodules generally diminished in size and in some cases disappeared, but seven out of ten cases showed evidence of mediastinal involvement. Cardiff Royal Infirmary reported five cases of recurrent carcinoma treated with comparatively large quantities of radium for one to three days. Three patients were relieved, one was unrelieved, and one died.

Cancer of the cervix is discussed from the point of view of statistics and of current technique. University College Hospital reported that in fifty-eight inoperable cases traced from October, 1921, to October, 1926, six patients were alive, three of whom had recurrences, and fifty-two had died, the average duration of life being fifteen months. Of thirteen operable cases, seven were alive and six have had no recurrences. Of twenty-two cases treated with radium and subsequently by Wertheim's operation five were alive without recurrences, and three who also survive, have developed recurrences at the end of fifty-four, fifty-three, and eighteen months respectively. St Bartholomew's Hospital reports on 196 patients treated with radium since May, 1921. In 146 cases the occurrence of haemorrhage before and after treatment was noted and it was found that it ceased entirely in 124, with the exception of a return shortly before death in some cases. Hyper-trophic growth disappeared in sixty out of sixty-nine cases noted. Of ninety-two cases of malignant ulceration this disappeared, temporarily or permanently, in sixty-two. Similar statistics are also reported from Birmingham General Hospital, Cardiff Royal Infirmary, and the Medical Women's Federation. Three main lines of technique were employed—namely, (1) the introduction of one or more radium tubes into the cervical canal supplemented by applicators packed round the cervix in the vaginal fornices, (2) the introduction of one or more radium tubes into the cervical canal tubes being inserted into the cervical tissues, and (3) the introduction of a large number of tubes of low radium content into the cervical tissues. The comment is made that the introduction of single tubes of radium into the cervical canal has been proved to be inadequate unless it is supplemented in one of the ways mentioned.

Cancer of the mouth, nasopharynx, larynx and oesophagus is dealt with in reports from St Bartholomew's Hospital, the Middlesex Hospital, King's College Hospital, Birmingham General Hospital, Cardiff Royal Infirmary, and Aberdeen Royal Infirmary. There was a considerable increase during the year in the number of patients of malignant disease involving these sites who were treated with radium. It is added that the combination of surgery with radium has not yet been fully exploited in these situations. The comment is made in the report from St Bartholomew's Hospital that primary growths of the mouth often yield to radium treatment, whereas the glands affected do not respond. It is thought that the resistance to radiation varies with the region where the growth arises and depends on some intrinsic quality of the tissues. The technique adopted in the case of carcinoma of the nasopharynx and larynx at St Bartholomew's Hospital is described in detail; it includes the making of a large window in the thyroid cartilage so as to allow the needles to be placed as close to the growth as possible.

Sarcoma of the rectum and bladder is the subject of reports from St Bartholomew's Hospital, Birmingham, King's College Hospital, Aberdeen, Cardiff, and St Peter's Hospital. At Birmingham twenty advanced and inoperable cases of carcinoma of the rectum were treated, seventeen being columnar-cell carcinoma. Improvement was obtained in four cases while eight were unbenefited and three patients died. The five remaining cases were too recent for any conclusions to be drawn. Colostomy is advised before treatment by radium is commenced, though removal of the cervix is not advocated. St Peter's Hospital reported upon the treatment of five cases of carcinoma of the bladder. In three cases no benefit resulted apart from the arrest of the haematuria, but in two cases there was also considerable improvement in the general condition.

Sarcoma and lymphosarcoma are considered especially interesting in relation to radium treatment because of the aim of the Radiology Committee of the Medical Research Council to establish some connection between the results of radium therapy and the histological character of the growths. Evidence has been obtained that many of the sarcomata are highly sensitive to radium, growths of considerable size diminishing when adequate doses are given. Among the lymphosarcoma, however, there appears to be great probability of the recurrence of the

growth. An impression has been received that round-celled sarcomata do not do so well as the spindle-celled varieties, but later information throws some doubt on this.

### Experimental Work

Experimental work was continued at the Radium Institute by Dr Mottin, who reported in investigation into the effect of beta radiations on Rous chicken tumour. He has also studied the action of these radiations on *Colpidium colpoda*. In the Middlesex Hospital report there is an account of experiments by Professor Russ and Miss Scott on the changes produced in the liver and tumour tissue of the rat by radon "seeds."

headache powders unnecessary. It could not replace endocrine extracts, but their administration could safely be combined with light.

Dr F Howard Humphris discussed the parts played by the chemist and physicist in actinotherapy, and prophesied that more would be discovered about the specific therapeutic effects of different wave-lengths of light and that the present clumsy method of using the whole light from any source would be abandoned. The wave-length of the light required for any particular treatment would be isolated by means of filters, which could, at the same time, serve as a protection to the patient. At present he thought such filters as existed in the ultra-violet region of the spectrum would "cut out the sunstroke-causing rays of Hindustan and give only the healthful rays of Honolulu."

The irradiation of foodstuffs and the relation thereto of vitamin D was treated by Professor I M Heilbron, who gave a few examples of research work in this field. It had been discovered that cholesterol itself was not a provitamin, but contained a minute quantity of another substance readily detected by means of the spectroscopic, to which the antirachitic properties were attributable. The provitamin was probably identical with ergosterol, a substance present in large amount in yeast and in a small amount in human and animal skin. Professor Heilbron emphasized the importance of team research in this new science of retinology, which promised to be so fertile in the treatment of disease. Professor Leonard Hill also gave an address on scientific research in relation to the practical energy of actinotherapy, dealing particularly with the relative sources of ultra-violet in sunlight and in artificial light.

## CONFERENCE ON "LIGHT AND HEAT IN MEDICINE"

WHAT was described as the first international conference on light and heat in medicine, surgery, and hygiene was held at the Central Hall, Westminster, from December 13th to 17th. It was organized by the *British Journal of Actinotherapy*, and the international character was given by the presence of four or five medical visitors from Paris and Berlin, who read papers. In the absence of Sir Alfred Mond the conference was opened by Dr F E Fremantle, M P, who sketched the enlarging field of actinotherapy, and especially the lead given to other countries by British medical men and scientists. He also referred, as did the chairman, Dr R King Brown, to the danger in untrained hands of the increasingly powerful arc and mercury vapour lamps. The sessions were well attended, some of them crowded, though it was stated that invitations had been issued only to medical practitioners and to others interested in the subject professionally, such as nurses engaged in the administration of light treatment under medical supervision.

At the first session a paper was read by Dr L G Dufestel on contraindications for ultra-violet therapy. He mentioned the great caution necessary if it was employed in pulmonary tuberculosis, and said that old persons with very brittle or rigid arteries ought not to be irradiated, nor patients with acute or chronic nephritis, nor cases of uncompensated myocarditis. A similar ban was placed upon light treatment in albuminuria. Certain skin diseases, such as acute eczema or lesions with bullae, might be found to be aggravated by ultra-violet light treatment. In addition, there were cases in which contraindications only made their appearance after preliminary treatment—for example, cases of tuberculosis in which the result of light treatment was the rapid appearance of intense pigmentation with a fall in blood pressure. In nervous patients, too, the treatment was found occasionally to aggravate the nervous condition.

Some recent advances in actinotherapy were described by Dr Albert Eidmow. A study of the effect of ultra-violet irradiation on the bactericidal power of the blood had convinced him that the maximum increase in this respect was obtained with a minimal erythemic dose of light and the irradiation of a surface area of skin corresponding to one-sixth of the surface area of the body. He had adopted a special line of treatment with lamps emitting shorter rays than 2,970 Angstrom units, exposing to a minimal erythemic dose two or three times a week successive areas of the body equal to about one-sixth of the surface, and allowing an interval of ten or fourteen days before repeating the irradiation on the same area.

The use of light in combination with other remedies was the subject of a paper by Dr F Heinaman-Johnson. He said that most therapeutic agents acted by stimulating the natural defensive powers of the body, and the benefit from the carbon arc was very similar to that from natural sunlight. Firing the carbon arc, a kind of "synthetic" light, might be produced by high candle-power incandescent lamps and non-erythem-producing rays from mercury vapour. He claimed that light treatment could imitate, at least in some degree, the effects of a great many drugs. It could take the place of iron and arsenic in anaemia and debility, of strychnine as a tonic, and, in a little time, it might even render the use of such things as

One session was occupied with the place of actinotherapy in public health work, Dr H Stanley Brink giving an account more particularly of the treatment of rickets by light at a welfare centre in Scotland. In some 120 cases treated with twenty or more light baths from both the carbon arc and the mercury vapour lamp, 95 per cent showed complete healing and the remainder partial healing. He held that artificial sunlight clinics at child welfare centres were well worth the trouble and expense involved, not only for the good in the individual case, but for their educative value to parents, who were led to appreciate what natural light and fresh air meant to their children. In school medical work actinotherapy was useful, and he had had experience also of its value in isolation hospitals, light was specially helpful in a general tonic after all acute fevers. The subject of rickets was also dealt with by Professor K Huldshinsky of Berlin, who spoke of the value of irradiation from the preventive point of view.

Among other contributions were papers by Dr Franz Nagelschmidt of Berlin on "bioluminescence," and Dr Jean Sudman of Paris on the therapeutic value of infra-red rays. Dr F W Edridge-Green gave a demonstration of colour vision, and several papers were read in a special section dealing with the eyes, including one by Dr J Spino on general, as distinct from local, ultra-violet irradiation in certain common eye conditions, such as keratitis and corneal ulcer. Although "heat" as well as "light" was included in the title of the conference, there were few papers on that subject, but Dr E P Cumberbatch gave an interesting account of recent advances in diathermy, drawing upon his experiences during a visit to America.

Concurrently with the conference an exhibition was held to which all the principal firms engaged in the manufacture of light apparatus and accessories appeared to contribute. The tendency of the new models of lamps shown was certainly towards portability. There were, in addition to lamps for treatment, many others for general or special illumination. An interesting exhibit was a lamp to exhibit by the Bermondsey Borough Council, which, as is reported in our issue of September 24th (p 565), has installed a solarium, equipped with a dozen carbon arc and mercury vapour lamps. The outcome, as Dr King Brown (medical officer of health for Bermondsey) told the conference, of a visit he had paid to the sunlight clinic of Dr Rollier at Leysin.

### CRIMINAL LAW AND INSANITY

ON November 16th the Lord Chief Justice began his David Lloyd Roberts Lecture on criminal law and insanity<sup>1</sup> by regretting that there should be any difference between the legal and medical professions in their views upon the actual and the proper attitude of the criminal law towards insanity. After a lucid exposition of the existing legal theory and practice Lord Hewart passed—strangely enough in view of such an opening—to a severely adverse criticism of the recommendations of the Atkin Committee a body which consisted of nine distinguished lawyers appointed by Lord Birkenhead when Lord Chancellor in 1922, in deference to the widespread uneasiness caused by the case of Donald Tru. That exclusively legal body far from emphasizing the cleavage between legal and medical opinion on this point actually endorsed the main recommendation on the subject submitted by a special committee of the British Medical Association—namely, modification of the Rules in *M'Naghten's* case by the recognition that a person charged criminally with an offence is irresponsible for his act when the act is committed under an impulse which the prisoner is by mental disease in substance deprived of any power to resist.

Publication of reports of the David Lloyd Roberts Lecture provoked some comment in the lay press notably a spirited apology for the Atkin Committee from Sir Herbert Stephen himself not the least distinguished signatory of its report which he characterizes as not dead as Dr John Cresswell in an earlier letter to the *Times* on the subject seemed to infer, but nearly five years old. We may take comfort in the reflection that as Sir Herbert Stephen observes legal reform in this country sometimes takes a long time arriving but arrives eventually nevertheless. Meanwhile we turn from the contemplation of so distant an event to a point upon which the Atkin Committee and Lord Hewart appear to be substantially agreed. In our opinion (say the Committee (referring to the report of a committee of the Medico Psychological Association in 1896) in 1923, as in 1896 to the insane person justice is done. This may well be, for the law has fenced the insane round with many safeguards other than the limitation of criminal responsibility set out by the Lords in the *M'Naghten* case. Juries are apt to make short work of legal definitions which run counter to their sense of natural justice—as Sir Herbert Stephen points out in the letter already quoted—and even we may add of obvious facts. If such excess of zeal may tend at times to the disadvantage of the accused there is always the Court of Appeal to correct so untoward a result whilst in cases not involving a capital charge the judge can apportion the punishment to the degree of criminality making allowance for the weakened or disordered intellect. Finally there remains the protection

conferred by Section 2 of the Criminal Lunatics Act of 1884 which provides for medical examination and certification of prisoners, and vests in the Home Secretary a discretionary power to act upon any certificate of insanity secured in such circumstances. Under this Act the Home Secretary has to consider primarily not the legal question of responsibility but the medical question 'What is the prisoner's present state of mind?'—a question the answer to which may well involve a review of the original finding as to responsibility.

But if to the insane justice is indeed done it is at times by ways which to the medical mind at least, would appear somewhat devious. This reflection is prompted by examination of page 5 of the *Times* of December 13th which contains reports of no fewer than five cases in which the question of the prisoner's sanity or insanity was a material issue. The opening of a sixth case of this class is recorded on another page of the *Times* of the same date. Three of the five cases were appeals from convictions of murder, of which two were dismissed by the Court of Criminal Appeal and one allowed.

The first two appeals call for little comment here. In the case of John Thomas Dunn the defence put forward at the trial had been that the dead woman committed suicide the issue of insanity had only been raised incidentally and counsel for the defence had not asked the jury for a special verdict. In these circumstances as the Lord Chief Justice said in dismissing the appeal a plea of misdirection on the ground that the judge had ruled that there was no evidence on which a special verdict could be founded was a plea wholly inconsistent with the defence and a *reductio ad absurdum* of appeals in murder cases. In the case of Rex v. Kirby—a second case of a murder in which the appeal was dismissed—the original defence had been one of insanity. The grounds of the appeal were certain alleged misdirections in the summing up. The Lord Chief Justice in delivering judgement said that in 1915 Kirby was discharged from the army as insane. Early in 1925 he underwent a serious operation which it was said, would be likely to increase his liability to a return of mental trouble especially in view of the fact that he had financial worries. The jury had before them the opinion of a doctor that Kirby was insane for just that space of time in which he committed the crime and they came to the conclusion that the defence of insanity had not been made out. There was no ground for complaint of the summing up and the application was refused.

In the third case the court allowed the appeal, substituting a verdict of Guilty but insane for the verdict of Guilty returned by the jury at Durham Assizes against Edward Lloyd a man who shot a police constable at Hilton Durham last June. The original defence had been one of insanity. At the hearing of the appeal Mr Paley Scott for the Crown said that Lloyd had shown no sign of legal insanity before the crime or after it and no medical witnesses were called at the trial to prove that he was insane. Commenting upon this failure to call medical witnesses Mr Justice Avery expressed the opinion that the evidence of ordinary witnesses is of a better than that of experts on these matters. At the original trial considerable sympathy was excited and the judge, after directing the jury as to the alternative verdicts open to them added that it would be right to return a verdict of guilty of murder with recommendation to mercy, in which case he, as presiding judge,

would be asked whether he agreed with that recommendation, which would not be lightly disregarded. Thus instructed, the jury returned a verdict of guilty of murder coupled with a strong recommendation to mercy, in the evident belief that such a verdict would prove the most merciful to the prisoner. The Court of Criminal Appeal, satisfied that Lloyd was actually insane when he committed the act charged against him, and that in all probability the jury would have found a verdict of guilty but insane had it not been for the direction of the judge, rectified the error. The Lord Chief Justice, in giving the judgement of the court, said that "Lloyd had been described as having been a 'very decent sort of chap' before the war. His military medical records showed that in 1916 he was removed from duty in the field in France suffering from exposure, exhaustion, and shock, and that after that date grave records were made of his mental condition. In September, 1925, he was described as having a childish mentality, and as being 'asocial,' unstable, and emotional. In 1926 he was said to be a 'congenital mental defective.' His wife said at the trial that he had always been a good husband, but that last Christmas he had attacked her with a rolling pin without any reason. On certain occasions he had seized his father-in-law by the throat, and, on being told afterwards what he had done, he had wept. Sometimes it had taken six or seven men to prevent his injuring himself and others."

We should have thought that there was here abundant material for the medical evidence which Mr. Justice Avois considers inferior to that of the ordinary witness. Possibly his attitude is determined by the fear expressed by Lord Hewart of a time when the decision of the question whether a great number of ordinary criminals should be held responsible to the law may be transferred to a section of the medical profession. We are not impressed by this fear. The legal definition of criminal responsibility and the scientific description of mental disease are and will remain different questions, but if full justice is to be done it will be well for the law to take cognizance of progress in medical as in other sciences. In this the Right Hon. H. P. Macmillan, K.C., chairman of the recent Royal Commission on Lunacy and Mental Disorder, would seem to agree with us, to judge by a statement he made when discussing the general functions of the expert witness, at the joint meeting of the Section of Neurology of the Royal Society of Medicine and the Medico Legal Society on December 8th. The law, he said, had learnt from medicine to discriminate with more justice, but it would never overtake medicine in the precision with which certain questions could be determined.

In the fourth case James Gillon, a gardener, was convicted at Sussex Assizes of the murder of his sister Anne Gillon, a maid employed in the same household. Evidence was given to the effect that after a disagreement with her brother the woman refused to get his supper one evening or his breakfast the next morning whereupon he attacked her with a razor, inflicting wounds from which she subsequently died in Hoxham Hospital. Dr. F. R. P. Taylor, medical superintendent at Hoxham Mental Hospital, called for the defence, said (we quote again from the *Times*) that "he had examined Gillon last Friday, and from the history prisoner gave came to the conclusion that he was a high grade mental defective, having developed premature degeneration of the nerve cells of the brain. He developed the idea that he was inferior to other

people, known medically as the 'inferiority complex.' He showed definite symptoms of delusion and persecution, which were progressive and were one of the forms of mental disease in which a patient was likely to develop homicidal tendencies. Probably the accused man knew legally he was doing wrong, but morally thought he was doing right." In reply to questions Dr. Taylor said that he thought Gillon knew he was taking the woman's life, but that he was undoubtedly insane. He did not show the slightest emotion when the dying depositions of his sister were read over to him. The jury returned a verdict of guilty, and sentence of death was passed.

In the last of the cases reported on December 13th Susan Eliza Turner, a chairwoman of 60, charged on indictment and on a coroner's inquisition with the slaughter of her daughter, a woman of 40, was found guilty by a jury and sentenced to ten years' penal servitude. The prisoner and her daughter had lived in a room in Walworth for many years past, both mother and daughter doing charring work until about ten months ago, when the latter disappeared and was not seen again. Apparently she was concealed during the whole period in the room shared with her mother until November 6th, when a fellow lodger and the landlady were called in by the mother, and the daughter was found in bed unconscious. A doctor was summoned, and the patient was removed to the infirmary, where she died on November 10th. The medical evidence was that the dead woman's body was very well nourished, that death was due to blood poisoning consequent upon an ulcer on the hip joint and general neglect, and that if she had had medical attendance her life would have been saved. In this case the jury had first to find whether the prisoner was insane so that she could not be tried. Dr. Morton, governor and medical officer of Holloway Prison, gave evidence that the prisoner had the mentality of a child of 6½ years. She was unable to answer quite simple questions, she had to count her fingers before she could say how many she had on her hand, she could not read or write, she did not know the date of the year, she knew that there were twelve pennies in a shilling, but she did not know a half crown, or how many shillings went to the pound. He thought she was unable to take any intelligent interest in her trial. Dr. Morton, when asked about the prisoner's statement that she locked the door "because she said that if I did not she would go out and make away with herself, she was very lazy and would not do anything for herself, she was old enough, I think, to shift for herself," said that this was practically the same reply that the prisoner always made—that the dead woman was old enough to look after herself.

On this evidence the jury found that the prisoner was not insane and was able to take her trial. On the prisoner being found guilty the judge (Mr. Justice Talbot) passed sentence of ten years' penal servitude, saying that it was necessary in her own interest to sentence the prisoner to a long term of imprisonment. In prison her health, mental and bodily, would be well looked after, and any special treatment she needed would be given her. His Lordship also expressed the opinion that, whilst the action of the jury had made it impossible to send the woman to a criminal lunatic asylum, that was where she would probably be sent ultimately, she would be carefully watched in prison.

So, in spite of difficulties, justice is being done to the insane. But whether the law has reason to be proud of its manner of doing so is a point on which opinions may differ.

## VITAMINS AND DISEASES OF THE EYE

Ever since the discovery of "accessory food factors" by Sir F. Cowdell Hopkins in 1912 it has been universally recognized that the lack of these substances now known as vitamins, in the diet leads to such marked disturbances of the general metabolism as to produce a number of definite and peculiar diseases—namely, rickets, scurvy, beriberi, and pellagra collectively known as the deficiency diseases. It has, however, not been so widely recognized that there are local as well as general disorders which can be included under the heading of deficiency diseases, and these may be well exemplified in the case of the eye certain diseases marked by eye symptoms having long been attributed by ophthalmologists to an ill balanced or deficient diet. These ocular disorders have recently been well described by Adair of Philadelphia. The three diseases of the eye described as being definite deficiency diseases are xerophthalmia (keratomalacia), certain forms of cataract and night blindness. Changes in the eye due to deficient or ill balanced diets similar to those now recognized as xerophthalmia were described under various other names long before the discovery of vitamins. As early as 1857 Dr Livingstone described an affection of the eyes in members of his party during his explorations in Africa, stating that "the eyes became affected (as in the case of animals fed in experiment on pure gluten and starch)." Again, in 1865 under the name of ophthalmia Brialmont, Cama Lobo described a disease of the eyes affecting poorly nourished slaves on Brazilian coffee plantations and in 1880 the Japanese observer Muro of Tokyo reported an epidemic of severe inflammation of the conjunctiva and cornea attributed to the absence of fat in the diet. Russian ophthalmologists have also ascribed the high incidence of certain inflammatory diseases of the eye in their country to the insufficient and poor food taken during the Lenten fasts. Again before the discovery of the fat soluble vitamin a somewhat similar disease was produced experimentally in the eyes of rats by Falta and Noeggerath in 1906 and this observation was confirmed by Knapp in 1909. This disease was thoroughly investigated by Mendel and Osborne in 1913, who proved that it was caused directly or indirectly by a diet deficient in the accessory substance which had by then come to be known as the fat soluble vitamin A. They also showed that by the addition of butter fat or cod liver oil containing the fat-soluble vitamin A the xerophthalmia experimentally produced in rats could be cured. The occurrence of xerophthalmia among rats has now come to be accepted as a criterion for the adequacy or the inadequacy of vitamin A in the diet. Rats which have been kept on a diet deficient in vitamin A for four to six weeks suffer from swelling of the lids and lacrimation. A discharge first becomes serous then purulent ensues. The cornea becomes cloudy, ulcerate and the eye is lost. Human xerophthalmia commences with the formation of white plaques on the conjunctiva constituting xerosis conjunctivae or Bitot's spots. Cloudiness and softening of the cornea follow with ulceration and loss of the eye although acute suppurative is seldom observed. It remains to be seen whether this human xerophthalmia is identical in origin with that of the rat but Bloch has described an outbreak of xerophthalmia in one division of an institution for children in Denmark. In all the divisions the diet of the children was identical except that in that affected it contained no butter, eggs cream or whole milk. When cod liver oil was added to the diet rapid recovery ensued. Again Widmark showed that practically all the butter made in Denmark was exported, and margarine came instead. In December, 1917, owing to the German submarine blockade the Government took over the control of all

the butter, which was then rationed so that everybody received 250 grams a week. From that date xerophthalmia practically disappeared. Whether other factors also enter into the etiology of xerophthalmia such as bacterial infection or the character of the inorganic moiety of the diet, as in the so-called "alt ophthalmia," has been much disputed, and McCollum and Simmonds express doubt "whether a deficiency disease ever occurs uncomplicated in man or animals." In addition to xerophthalmia, certain cataractous changes in the lens have been considered to be dependent on a vitamin deficiency, but the evidence is conflicting. Night blindness has also been described as a symptom often observed as accompanying or preceding xerophthalmia. Night blindness is, however, a symptom which occurs in many diseases under varying conditions. A consideration of its pathological physiology, however, indicates that in all cases we are dealing with some disturbance of what Sir John Parsons terms the scotopic mechanism—that is to say with some defect in the functions of the rods and visual purple. Night blindness is often associated with xerophthalmia, but may occur in its absence. It is of interest to note that the treatment of this condition dates back to Hippocrates who recommended the use of liver in abundance which is now known to be rich in the fat-soluble vitamin A. The subject has also been studied experimentally in the rat and a consideration of the results obtained would show that vitamin A starvation in rats produces a defect in the functions of the visual purple as shown by its slow regeneration after it has been bleached through exposure to intense light and that this abnormality occurs at an earlier date than do the pronounced symptoms of xerophthalmia.

## LONDON WATER

The Royal Society of Medicine held a social evening at 1 Wimpole Street on December 14th when the president, Sir James Berry, and Lady Berry received a large number of Fellows and guests. The feature of the evening was a lecture by Sir Alexander Houston, director of water examinations Metropolitan Water Board who spoke on the romance of London's water supply. In the library the method of chlorination of the water was demonstrated in a small plant and there were other exhibits, some of them dating back to a pre-scientific era such as a wooden water main which had been excavated from the neighbourhood of the society's house and had probably been laid in the reign of William and Mary. On more than one occasion, in reviewing Sir Alexander Houston's lively reports on a subject which in any case could not be called dry, we have commented on the fascinating story of the watch on the river. Sir Alexander Houston asked his audience whether the word "romance" was ever more fittingly applied than to the task of supplying a highly purified water to the great population of the metropolis. The magnitude of the task is itself romantic. The storage reservoirs of the Metropolitan Water Board number 49 covering 2,704 acres and holding 20,000 million gallons. The crude reservoirs number 91 covering an equal number of acres and holding 323 million gallons. There are 172 filter beds covering as many acres, engines of a total of 4,600 horsepower, and water mains extending for 6,725 miles. The result is to bring to the taps of London every day 250 million gallons, or 37 gallons for each inhabitant. Sir Alexander Houston pointed with pride to the virtual absence of typhoid fever from the county of London during the present century, though there had been epidemics in the provinces, notably at Lincoln in 1905. He did not claim that this result was entirely or mainly due to improved water supply, it was due to an improvement in sanitation generally, but he thought the waterworks engineer could claim some of the credit. Thames water, which accounted for 60 per cent

of the London supply, was purified by storage, chlorination, and sand filtration. There had been a wonderful improvement, he said, in the quality of the water consequent upon storage. Some telling slides were exhibited, contrasting, for example, Thames river water before storage and Chelsea storage water, on the *B. coli* test the latter showed an improvement of at least one hundred times. Unfortunately, storage encourages the development of algal and other growths in the reservoirs, such as *Asterionella*, *Fragilaria*, *Dinobryon*, *Oscillaria*, and *Tabellaria*. These, while quite harmless, give rise occasionally to taste troubles. One method of overcoming this is to treat the water with innocuous chemicals suspended in sacks over the sides of a boat, which forms the reservoir until the chemical is dissolved. The filtration process is also full of interest, it is very slow, less than two gallons of water per square foot per hour being filtered, the filter bed seen in section shows 36 inches of fine sand, below this 12 inches of coarse sand, then 9 inches of fine gravel, and 9 inches of coarse gravel. With regard to chlorination, this process, it will be remembered, was first adopted on an extensive scale during the war, mainly to save coal used for pumping, but the result also was to yield a better water bacteriologically than would have been the case had it undergone prolonged storage. Sir Alexander Houston did not forget to pay a tribute to Sir Hugh Myddelton, who, at the beginning of the seventeenth century, conferred a great boon upon London by bringing thither the New River from Amwell and Chiswell in Hertfordshire. He described Myddelton as truly one of the pioneers of preventive medicine. Sir William Hare-White, in proposing a vote of thanks, said that the audience must be extremely grateful for the lecture, and still more for the achievement which the lecture narrated, even though some, like himself, felt chastened because they had known so little and taken for granted so much.

#### THE PROTECTION OF MOTHERHOOD

In 1923 Dame Janet Campbell, senior medical officer for maternity and child welfare, Ministry of Health, produced two reports bearing on the subject of maternal mortality, one dealt with the education of the medical student in obstetrics, and the other with the training of the midwife. In the following year a further report by her, on the causes of an excessive maternal death rate and the means for its reduction,<sup>1</sup> was issued by the Ministry, and a notice of it appeared in the *BRITISH MEDICAL JOURNAL* of April 12th, 1924 (p. 682). That report aroused great interest in the medical profession, and some of its statements and implications were strongly criticized, more particularly by general practitioners. Seldom indeed has a public medical document led to so much controversy in our columns and elsewhere. One effect was a resolution by the Council of the British Medical Association, adopted on December 17th, 1924, declaring that it could not accept the opinions expressed in Dame Janet Campbell's report as to the causation of puerperal morbidity and the influences which had been drawn therefrom. Another effect was the appointment by the Council of a special committee to inquire into the matter generally. That committee has met many times since its first appointment in February, 1925, and an interim report by it appeared in the *SUPPLEMENT* to our issue of January 9th, 1926. We now have to record the issue this week by the Ministry of Health of another report from Dame Janet Campbell, supplementary to the last, and entitled *The Protection of Motherhood*. In it she reviews the existing position of the problem in England and Wales, supplies the latest available statistics, discusses anew the vexed question of puerperal infection

as illustrated by a number of recent outbreaks, and sets out what she regards as the necessary provisions for a complete maternity service. Her concluding paragraph speaks of the protection of maternity as being part of a comprehensive scheme of safeguarding and improving the public health, "but it is basic and fundamental because it is only upon a foundation of healthy, happy, and contented motherhood that we can hope to build up a Nation sound in mind and body. We shall be wise, therefore, to neglect nothing which will ease the burden of childbearing and relieve it, as far as may be, of its weariness and its dangers." A prefatory note is contributed by Sir George Newman, Chief Medical Officer of the Ministry of Health, and an appendix on the pathology of puerperal pyrexia by Dr. Arthur Eastwood, senior bacteriologist to the Ministry. The report will no doubt be studied with close attention by the medical profession at large, and not least by general practitioners. Meanwhile we reserve comment to a later issue.

#### FRENCH VITAL STATISTICS

ONE of the most valuable of the series of statistical handbooks issued by the Health Organization of the League of Nations deals with the official vital statistics of the French Republic. There are considerable differences between French and English practice, and a general outline of the French procedure will be interesting. In France the census, which is taken quinquennially, is designed, first, to enumerate the legal population of areas for the purposes of government and taxation, and secondly, to ascertain specified data regarding all persons. Since 1896 the institution has been to concentrate on civil condition and occupation in alternate censuses. In 1921, however, the census included both. The census agents, appointed by mayors of communes, are each responsible for a district containing from 100 to 200 persons. The census agent makes preliminary inquiries, issues, recovers, and checks the schedules, of which one is prepared for each person, and delivers them, together with a house bulletin and memorandum, to his census supervisor. The supervisor sends them, with a summary report, to the mayor of the commune. The mayor prepares a nominal roll of the inhabitants in duplicate, retains one copy for the communal archives, and forwards the other, with a summary statement and all the schedules, to the prefect of the department. The accumulated papers are finally sent by the prefect to the General Statistical Office of the Ministry of Labour, where they are centralized. The results are published as the census report. The prefects also prepare departmental summaries, which are consigned to the Minister of the Interior. The birth of a living child must be declared within three days by the father, or in his absence or default by the doctor or other person, on pain of fine or imprisonment. The declaration is made to the registrar, who draws up the *acte de naissance*. There are special provisions for the recognition of illegitimate children by their parents. Stillbirths must be similarly declared, but it is not now necessary to submit the body to the registrar. A death must be declared before the registrar by a relative of the deceased or other appropriate person. Declaration, by custom, is made within twenty-four hours, but no time limit is prescribed. The mayor of the commune or his deputy is the sole competent authority for drawing up the *acte de décès*. The body in all cases must be viewed by an authorized verifier, to verify the fact of death, but premature burial occurs. The *acte* contains no information as to the cause of death. As the medical practitioner in attendance is not required to give a certificate—though some do—the medical or other verifier who views the body endeavours to trace the cause of death by inquiry.

<sup>1</sup> Reports on Public Health and Medical Subjects. No. 25. *Maternal Mortality*. By Janet M. Campbell, M.D., M.S. London: H.M. Stationery Office, 1924. 1s net.

<sup>2</sup> Ibid. No. 28. *The Protection of Motherhood*. 1927. 9d net.

reliability of the data so recently varies, and the official record in some cases may merely reflect the views or relations of neighbors. The sole official list of causes of death is the "Abridged Interim Report," which contains thirty-eight numbers. The registrar in most communes draws up a special bulletin setting forth, among other facts, the cause of death. The mayors of communes transmit the bulletins drawn up by their registrars together with a covering summary, to the prefect of the department, and the prefect hands them on also with a covering summary, to the General Statistical Office. The general mortality returns are published in the *Statistique du Mouvement de la Population*. The infectious diseases compulsory notification in France are eighteen in number. They include not only the diseases named in the English Infectious Diseases Notification Act with the addition of plague, yellow fever and one other. For nine further diseases notification is optional. Responsibility to notify rests with medical practitioners, public health officers and midwives. Notification is required to be made, forthwith and in duplicate, one form to the prefect or subprefect of the department and the other to be mayor of the commune. Notification forms in the shape of letter cards with counterfoils made up in book are issued free. In order to ensure prompt action the disease is referred to by number only according to a list of numbered diseases printed inside the cover of the book of cards. The practitioner is under penalty if he fails to notify; he is under penalty also if he intrudes medical confidence in this dilemma it is understood that he sometimes withholds notification. A register of notifications is kept by the prefect who sends a monthly summary to the Department of Health of the Ministry of Labor. A general statement based on the summaries is published annually. In most departments and big towns a bacteriological laboratory service is provided for medical practitioners free of charge. In diseases compulsorily notifiable disinfection also is compulsory. In the case of poor persons it is carried out free of charge. Others pay on a sliding scale according to income and size of house. In diseases optionally notifiable disinfection may only be carried out with the consent of the families concerned. Vaccination and two revaccinations are compulsory in France. For pulmonary tuberculosis, which is one of the optionally notifiable diseases there are 500 dispensaries and 54 sanatoriums with 7,000 beds. For venereal disease, which is not notifiable, dispensaries have been organized and special facilities are provided for pregnant women nursing mothers, soldiers, sailors, sailors and prostitutes.

#### TRISTAN DA CUNHA

In connection with the little exhibit of Tristan da Cunha in the South African pavilion at the British Empire Exhibition a handbook was prepared by Mr. Denis M. Kane. He has now brought out a further edition describing the place in the Empire of this loneliest British possession, the condition of its inhabitants and the efforts that are being made, especially by the Tristan da Cunha Fund and the Society for the Propagation of the Gospel for their welfare. The 150 people who live on this extinct volcano in the South Atlantic do not appear to be completely isolated from the rest of the world as formerly. From time to time big liners crossing the Atlantic on world tours call at the island and have letters and stores, so that there is hope that the inhabitants may escape in future the severe privations to which in the past they have been exposed. The Tristan da Cunha Fund hopes to achieve these ends by establishing periodical communications with Cap Colony to form an affiliated settlement on the South African mainland and to cultivate the interests of an administrative authority with benevolent ultimate

jurisdiction vested in a visiting warship. Some years ago a proposal was made to transfer the population to the mainland but many refused to leave their homes, notwithstanding the hardships to which they are constantly exposed. Mr. Kane suggests that an affiliated settlement would relieve conditions on the island whenever the number of people exceeds its capacity to sustain them. Moreover, whether we agree or not with his view that Providence has designedly put such places as Tristan da Cunha in our hands for the purpose of protecting the British Empire, there may be something in his contention that such outposts may one day prove a civil as a second string to the Sure-Civil. The men of Tristan da Cunha have on several occasions been of assistance to shipwrecked mariners. For these reasons a periodical visit by a warship conveying stores to this outpost of empire, may well be justified.

#### CHINESE HOSPITAL, SHANGHAI

The time has come when there are given the chance of doing so is illustrated by the annual report for 1926 of the Chinese Hospital in Shanghai. This institution is controlled by British trustees and staffed by members of the London Missionary Society. The eighty-first annual meeting was held early in June and the chairman expressed the hope that within a year the projected rebuilding would have become a fact. Under the will of Mr. H. Foster, a British resident in Shanghai who died in May 1926 an adequate sum has been provided for the replacement of the present old and inconvenient buildings by a well equipped modern hospital. It is proposed to begin the work of reconstruction before the end of this year and efforts will be made to continue the activities of all the hospital departments during the rebuilding period. A convalescent home is to be established shortly in the outskirts of the settlement in order to give both the patients and members of the staff the advantages of change of air and scene. Dr. C. J. Davenport who died in September 1926 began work in the Shanghai Hospital in 1904 and was primarily responsible for the great advances subsequently made. Dr. H. Fowler who has been the acting medical superintendent since the death of Dr. Davenport comments on the increased work thrown upon the hospital by the armed robbery and assaults which in spite of all the efforts of the excellent Shanghai police have filled the surgical wards with seriously injured Chinese men, women and children. He adds that casualty work always a notable feature of this hospital has continued to increase with the growing congestion of traffic in the crowded tortuous and narrow streets of the settlement. In the section of the report devoted to the women's hospital it is announced that an annual physical examination has now been arranged for the Chinese women nurses; this has been found essential in view of the prevalence of tuberculosis in China where the girls are without the early physical training and outdoor habits of their British contemporaries. With the provision of the new convalescent home it is hoped that nurses showing consumptive tendencies will be able to overcome them.

#### THE EDITOR OF THE BRITISH MEDICAL JOURNAL

The Council of the British Medical Association at its last meeting on December 1st received the resignation of Sir Dawson Williams M.D. LL.D. D.Sc., who will shortly complete his thirtieth year as Editor of the British Medical Journal and who before his appointment to that post in January, 1923 had for sixteen years been connected with the Editorial Department. At the same meeting the Council appointed Dr. V. G. Horner, who has been Assistant Editor for the past eleven years, to succeed Sir Dawson Williams as Editor.

## Nova et Vetera.

### RICHELIEU AND THE SORBONNE

THREE hundred years ago Richelieu approved the plans of the architect Lemercier for the reconstruction and enlargement of the Sorbonne, the college which had been founded in 1257 by Robert de Sorbon. The fame of this great Paris institution is known throughout the learned world, but probably few could give an account of its history. It is therefore opportune that Professor G. Dupont-Ferrier, of the Ecole des Chartes, now lodged in the building, should have celebrated the anniversary by contributing an illustrated article to the *Revue Scientifique* of Paris.

Robert de Sorbon, whose parents were peasants in the Champagne, became chaplain to Louis IX, over whom, though he was little of a courtier, he had great influence. He established his college as a home for students and teachers at a date probably earlier than any college at Oxford or Cambridge, and he left to it his name and his fortune. His desire was to help poor students and teachers in theology, and to counter the monopoly of power enjoyed at that time by the mendicant friars. Consequently many of the distinguished early teachers in the Sorbonne were strong adversaries of the mendicant orders. The students for whom Robert de Sorbon provided had long been the victims of predatory lodging-house keepers, who increased the students' difficulties by letting adjoining rooms to *filles de joie*. With aid solicited from the King, the Queen, nobles, prelates, and foreigners, Robert was able to establish his *pauperum domus*. His regulations remained in force down to the time of the French Revolution.

The personnel of the college was formed of foundation scholars, foreign students who paid their way, associates, and guests. The last named had no part in the administration of the community, but hoped to be incorporated in the ranks of the Sorbon, who remained associates for the whole of their lives. The governance of the college was in the hands of a master, assisted by a prior who maintained discipline, and a proctor who managed the finance. A registrar and a librarian completed the governing body, all the offices except that of master were annual appointments. The offices were controlled by three councils, one to supervise the observance of regulations, the second for finance, and the third concerned with the discipline and good behaviour of the students. All the members of the community met together at various assemblies. In the fifteenth century two-thirds of the masters in theology belonged to the Sorbonne, and in the sixteenth century its authority had become so great that difficult cases of conscience were submitted for its decision. Many of its professors were not only doctors in theology, but also in law and medicine. The position of the college became so important in theology that it has sometimes been confused with the Faculty of Theology in the University, an error into which even such men as Luther, Pascal, and Voltaire fell.

A library was attached to the Sorbonne by its founder, and it was at the Sorbonne that the first printing presses in Paris were installed. The greatest care was taken in the preservation of the books in the library, but lending was allowed under strict precautions. While most of the colleges founded later only admitted students from certain provinces, dioceses, or towns, the Sorbonne, like the University of Paris, welcomed from the first the attendance of foreigners.

To this foundation of Robert de Sorbon, cardinal-duke Richelieu was appointed master in 1622. Richelieu, who was born in Paris, was not a Sorboniste but was educated at the royal college of Navarre. Nevertheless, he became imbued with a deep affection for his adopted college, desiring to give it a more worthy home, he, with the help of Lemercier, converted the cloister of Sorbon into the Palace

of Sorbonne. The original site of the buildings was retained, but was increased by one third towards the south. The new construction was in the form of an irregular quadrangle. Richelieu's white stone and red brick edifices remained until it was pulled down and rebuilt at the end of last century. Now all that remains of his building is the chapel, which contains Richelieu's tomb, the work of Girardon (1694). But the Sorbonne of Richelieu, the college for students of theology, was destroyed during the revolution (1792), though teaching in this and other subjects was resumed in 1821. In addition to the library, the buildings now house the Ecole des Chartes.

During its long career the Sorbonne, according to Professor Dupont-Ferrier, maintained its traditions of frugality, poverty, work, and modesty. The Sorbonistes took their meals in common, with friendly discourse; they played tennis together in their garden. Poverty was accepted as one of the most solid of the virtues. Often the revenues of the college were insufficient to meet its needs, and money was saved by suppressing a course at meals, by going without fires and lights in some of the rooms, the library, or the staircases, or by making the old cassock last a little longer. Work in teaching was arduous, so that even the most distinguished Sorbonistes published but little in comparison with the professors of other colleges. They were faithful to the vow of Robert de Sorbon to live only for their pupils.

The confusion which arose between the Faculty of Theology and the Sorbonne—a confusion which even led to such loose appellations as doctor of the Sorbonne instead of doctor of theology—arose mainly from two causes. The Faculty of Theology had the duty of supervising the publication of new books, and for a long time this duty was discharged by professors of the Sorbonne. Secondly, the Faculty of Theology was in the habit of attending at the hall of the Sorbonne for the purpose of hearing theses for licentiates in theology. The presentation of his thesis must have been an ordeal for the candidate: his examination, in the presence of theologians and strangers, lasted for twelve hours, during which time the judges replaced one another in having tips for the unfortunate student. An additional cause of confusion, perhaps, came from the fact that up to the end of the ancient regime the Sorbonne maintained its autonomy. Its independence was such that in 1666 the college refused to open its doors to the rector of the University of Paris, and within its threshold even the powers of the King were limited.

At the present time the Sorbonne is the home in Paris of the Faculties of Science and of Literature, as well as of the Ecole des Chartes, which is a school of history, but combines with that some of the functions of the Record Office in London. In the past and in the present, says Professor Dupont-Ferrier, the Sorbonne has worked for the great and good renown of France.

## New South Wales.

### HOSPITALS AND INJURED WORKERS

THE Workers' Compensation Act, 1926, contained a provision whereby medical fees up to £50 were a charge on the employers but the Act was so worded that the medical practitioner, unless directly employed by the employer, was unable to collect fees except from the injured worker. As a result the employer or insurance company, as the case might be, promptly ordered the injured worker to go to a public hospital for treatment, although they did not support the public hospitals financially. This naturally led to considerable irritation, both among medical practitioners and hospital authorities, who felt that the insurance companies were evading the provisions of the Act and were making unfair use of public charities. In March, 1927, an amending Act was passed, containing the following clauses:

- 1 The worker shall notify the employer without undue delay that he has obtained treatment and the cost of such treatment to the employer shall be limited to £50 unless the Commission otherwise directs.
- 2 If the worker obtains medical treatment for himself or his family, he shall be entitled to have the worker examined by a medical practitioner by the employer in consultation with the worker's medical adviser.

American College of Surgeons, while on a visit to the hospital recently, recommended the following basis for such a scheme

(a) That there should be various grades of accommodation and charges

(b) That the question of professional charges should be a matter between the doctor and his patient

(c) That those who voluntarily enter paying wards of the hospital and those who are deemed by an investigating official of the hospital to be able to pay professional fees in addition to maintenance, should make their own arrangements for attendance with the doctor of their choice, and should not be under the medical or surgical control of the resident medical staff

(d) That private patients entering wards should not be attended by the stipendiary staff, but by the doctor of their choice. Fulfilling such a choice being made nothing should prevent a member of the honorary staff from attending the patient in a private capacity

## England and Wales.

### KING EDWARD'S HOSPITAL FUND

THE annual distribution meeting of the King Edward's Hospital Fund for London was held on December 13th, with the President, H R H the Prince of Wales, in the chair, for the purpose of awarding grants to the hospitals and convalescent homes for the present year.

The Prince of Wales read a message from the King congratulating the Fund on increasing its distribution from £245,000 to £247,000, with the help of the League of Mercy, which was contributing £17,000 instead of £15,000. Commenting on the increase, the Prince expressed his gratification at this forward step by the League of Mercy, and his thanks to the British Charities Association for its donation of £15,000. One anonymous gift of £8,000 had been received during the year by the General Fund, legacies had increased by £10,000, and the income from investments had risen by £3,000. The capital fund continued to grow, the largest addition to the investments this year being Mr H W Marshall's gift of £10,000 conversion stock. The total distribution for 1927 amounted to £281,500, including a sum of £34,500 from the legacies of the late Mr and Mrs Wells, which was being devoted to schemes of extension and improvement. These legacies had already helped to provide more than 1,300 additional beds, including 144 for accident cases. The Distribution Committee had been studying the problem of providing immediate medical attendance for accidents and other emergencies, and it was proposed that the conclusions reached should be published. The annual statistical report on the financial state of London hospitals had been issued (Reference to this was made in our columns on November 5th). During 1926 hospital expenditure had continued to expand with the increasing number of beds, while the income was slightly less, a small deficit had appeared, therefore, this year for the first time since 1922, chiefly due to a falling off in legacies. Contributions from patients had continued to grow, and were being received at the rate of £220,000 a year. The Prince referred to the Pay Beds Committee of the Fund, which was inquiring into the question of hospital accommodation for people with incomes above the ordinary, and also to the pensions scheme for nurses and hospital officers, which would begin on January 1st, with eighty-nine London hospitals, representing more than 12,000 beds.

Lord Revelstoke, honorary treasurer, stated that, contrary to anticipation, it had not been necessary to make use of the whole of the £9,000 added to the reserves in 1925. In consequence of some unexpected contributions the withdrawals had been limited to about half this amount. With regard to the Wells legacies £214,240 had been received so far on account, and it was believed that these legacies would amount eventually to more than £240,000. Lord Inglegh had bequeathed £60,000. Sir William Collins stated that since 1899, when the League of Mercy was established, it had distributed to voluntary hospitals £515,731, of which £415,034 had been given to the King's Fund. The increased grant this year was rendered possible by the generosity of subscribers.

Lord Somerleyton, honorary secretary, presented a schedule containing a list of awards to hospitals, including

recovery and convalescence branches. Among the largest grants were

The London Hospital £16,150, Guy's Hospital, £11,500, Thomas's Hospital, £11,000, Royal Northern Hospital, £9,700, Middlesex Hospital, £8,825, St George's Hospital, £7,900, King's College Hospital, £7,500, St Mary's Hospital, £6,750, Royal Free Hospital, £6,500, St Bartholomew's Hospital, £6,000, Westminster Hospital, £5,750, Prince of Wales's General Hospital, £5,600, Charing Cross Hospital, £5,500, Queen Mary's Hospital for the Last End, £5,200, Metropolitan Hospital, £5,000, Westminster Hospital, £5,000, Miller General Hospital, £4,575, Royal National Orthopaedic Hospital, £4,500, and the Queen's Hospital for Children, £4,050.

### DURHAM UNIVERSITY MEDICAL SOCIETY

The annual dinner of the Durham University Medical Society was held at Newcastle in the University Union on December 15th, with Mr Harvey Evers, president, in the chair. The chairman, in proposing the toast of "Our Guests," made special reference to Professor Thomas Beattie and Sir Thomas Oliver, whose names were received with acclamation. He said that it was a great shock to them to know that Professor Beattie was retiring from the staff of the Infirmary. Professor Beattie had been born, bred, and educated in the city, of which his father was at one time mayor. The loss was very great to them, though they had the pleasure of knowing that he was remaining awhile as consulting physician. It was also a great satisfaction to know that his services would not be lost to the University. Professor Beattie, in acknowledging, said that his severance from the Infirmary was due to the fact that the calendar told him he was older than he felt. Though giving up his clinical activities, he hoped to teach for some years to come. His association with the Infirmary had been continuous since 1886, while his connexion with the society commenced in 1888, when he was its secretary and afterwards president. Sir Thomas Oliver, in proposing the toast of "The Medical Society," said that medical men of the present generation had fuller opportunities for participating in public life than heretofore, and their services would be of great practical value in Parliament. Mr T A Hindmarsh expressed the indebtedness of the members of the society for the heavy labours of the president and secretary on their behalf.

### MANCHESTER TRIBUTE TO DR MCGOWAN

On December 16th a large company of Manchester medical men and women met at the Grand Hotel at a dinner in honour of Dr R G McGowan, who retires this month from the secretaryship of the Manchester Medical and Panel Committee, which he has held since the inception of the Insurance Act. Dr Skinner, the doyen of medical men in practice in Manchester, took the chair, and was supported by Mr A H Burgess, Dr Dunn, chairman of the Insurance Acts Committee, Dr Frank Radcliffe, representing the Lancashire panel practitioners, and Dr G C Anderson, Deputy Medical Secretary, in the absence, owing to recent bereavement, of Dr Cox. Mr Walter Davies, J P, the first and only chairman of the Manchester Insurance Committee, was the only layman present. The toast of the evening was proposed by Dr T A Goodfellow, who recounted some of the doings of Dr McGowan as secretary, representative of panel practitioners on the Manchester Insurance Committee, as adviser in cases before the Medical Service Subcommittee, as member of the Insurance Acts Committee, and as sage counsellor and friend of all in time of doubt and difficulty, and presented to him on behalf of the practitioners of Manchester a gold cigarette case suitably inscribed, containing a cheque for £1,000, together with a platinum and pearl necklace for Mr McGowan. The presentation led to a scene of enthusiasm, showing conclusively the admiration and esteem of his colleagues. Dr McGowan's response was very brief and lacked much of the incisiveness and vigour usual in his public speeches, to the amusement of many with whom he had dealt faithfully in times gone by. The toast of the guests was proposed by Dr Coulthard, whose speech at the Edinburgh dinner will be remembered by many, and responded to by Drs Dunn, Radcliffe, and Anderson. As Mr Walter Davies had to leave to catch a train, Dr Edmund Johnstone responded on his behalf.

## A BLOOD TRANSFUSION SERVICE IN LONDON

The British Red Cross Society has recently published a special report on the blood transfusion service, which has been carried on under its auspices since 1925. The foundations of the present service were laid in 1921 when a request was received by the Camberwell Division of the British Red Cross Society for a blood donor for a case of emergency, and soon numbers volunteered. Mr P. L. Olivier, honorary secretary of the division, collected about twenty volunteers for subsequent cases, and has maintained the necessary organization since then. In 1922 thirteen transfusions were given, in 1923 twelve, and in 1924 the number increased to sixty-two. An appeal for volunteers was made to the general public, and thirty responses were received, one from a boy scout who interested his organization in the work. In 1925 a total of 389 transfusions were supplied, of which 277 were given by boy scouts. In 1926 477 were supplied by boy scouts and 159 by members of other organizations. At the present time the number of donors enrolled is approximately 450, about sixty of whom are women. After each transfusion the hospital supplies clinical information as to the result, and this is duly recorded. Medical practitioners may obtain full information from the secretary, Mr P. L. Olivier, 210, Peckham Rise, East Dulwich, S.E.22. The report gives a list of the sixty-eight institutions from which applications were received during 1926. The Blood Transfusion Service has been financially self-supporting from the start. The bulk of the income is derived from donations, the sale of or time for collection, and from the organization of entertainments. The British Red Cross Society hopes to form similar services all over the country.

## Ireland

## ULSTER MEDICAL SOCIETY ANNUAL DINNER

The annual dinner of the Ulster Medical Society was held in the Medical Institute, Belfast on December 15th. The president, Dr J. C. Rankin (Belfast) occupied the chair, and a company of about 120 was present. After dinner the toast of 'The King' was duly honoured and the president then gave the toast of 'Prosperity to Northern Ireland' which was responded to by the Right Hon. E. M. Archdale, Minister for Agriculture for Northern Ireland. 'The Royal Colleges of Ireland' was proposed by Mr S. T. Irwin, F.R.C.S. Ed. (Belfast), and responded to by Dr W. A. Winter (Dublin), President of the Royal College of Physicians of Ireland, and by Mr A. Fullerton (Belfast), President of the Royal College of Surgeons in Ireland. The health of the guests was proposed by Prof. C. G. Lowry and responded to by Mr John McGonigal, K.C. and by Mr D. Wilton Smith. The president's health was proposed by Dr Foster Coates (Belfast) and responded to by Dr Rankin who asked the company to join him in drinking the health of their honorary secretary, Dr Marjand Beith on whom so much of the hard work had fallen.

## NOTIFICATION OF INFECTIOUS DISEASE

In a letter to each sanitary authority in the Free State the Minister for Local Government and Public Health states he has had under consideration the adequacy or compliance with the requirements of the Infectious Diseases (Notification) Act, 1889, and he has formed the opinion that a result of correlating the registered deaths with the statistics of the known incidence of the graver epidemic diseases (enteric fever, diphtheria and scarlet fever) that the duty of notification is insufficiently observed. Furthermore, a comparison between the records for urban and rural districts goes to show that the deficiency of notification is more clearly marked in the latter areas. In the circumstances the Minister desires to impress on sanitary authorities the importance of a strict enforcement of the notification system. Attention is directed to the circular letter of May 28th 1925, intimating that uniform application throughout the Irish Free State (Sorstat Eireann) was given by the Local Government Act of that year to the

obligation to notify infectious disease—namely small pox, cholera, diphtheria, membranous croup, erysipelas, scarlet fever, and the fevers known as typhus, typhoid, enteric relapsing continued, or puerperal. It should be realized that notification is not only essential for the protection of the public in facilitating disinfection and other precautionary measures, but in the interests of the individual patient himself, the medical officer of health to assist in arranging for suitable institutional accommodation and nursing attendance where necessary. It is suggested that general notice of the duty of notification and of the liability to penalty in case of default should be given by the sanitary authority to members of the medical profession and to the public at large by advertisement in the local press and such other means as may be considered advisable. It may also be explained that upon the appointment of a county medical officer of health he becomes entitled to receive notification of infectious diseases in substitution for the dispensary medical officer (Article 9 (7) of the County Medical Officers of Health Order 1926) and it will devolve upon him from time to time to undertake a critical survey of the practical working of the notification system in the county for which he acts.

## ORGANIZATION OF THE CO. FERMANAGH DIVISION

A very successful meeting of the members of the Enniskillen or Co. Fermanagh Division of the British Medical Association was held in Enniskillen on December 15th. Many of the members who attended had only just joined and their recruitment was entirely due to the efforts of Dr Leonard Kidd who entertained the company at dinner at the Imperial Hotel, Enniskillen. The Irish Medical Secretary (Dr T. Heune) was present and gave an account of the aims of the British Medical Association and what it had done for the profession in Ireland. A vote of condolence was passed to Dr Alfred Cox, Medical Secretary, on his recent bereavement.

## Scotland.

## REGISTRATION OF MATERNITY HOSPITALS AND HOMES

The Scottish Board of Health has issued to local authorities in Scotland regulations dated November 24th 1927 prescribing the necessary forms for compliance with Part II of the Midwives and Maternity Homes (Scotland) Act 1927. Under the Act and Regulations every maternity hospital and home will require to be registered by the local supervising authority of the area in which it is situated and will receive a certificate of registration as from January 1st, 1928. The Regulations prescribe the particulars which must be entered in the registers to be kept in such maternity hospitals and homes. Copies of these may be obtained from H.M. Stationery Office, price 2d. The general regulations connected with registration were outlined in our columns on November 5th (p. 347). The points which have to be entered in the registers to be kept by the homes are the names of medical practitioners attending the patients or infant children in the home, the names of other persons attending on the home, the names of each patient and of the infant children or such patients and the names of all children born in the home who are removed from the home to the custody of other persons than the parents, guardians or relatives. The last part is known as the removal register. Case records must also be kept showing a daily statement of the health of the patients and children and also a record of the amount of payments made to the keeper of the home by, or in respect of, patient. Notice of deaths at the maternity home must also be sent to the local supervising authority within twenty-four hours of their occurrence. The form which the various registers are to take is given in the Regulations.

## MEASLES IN GLASGOW

A bulletin issued by the public health authorities of the city of Glasgow shows that at the present time there are 2,560 notified cases of measles in that city as compared with 65 at the corresponding period last year. The incidence

of the disease is spreading at the rate of about 800 or 900 cases each week. Although the distribution of cases is fairly general, the eastern, south-eastern, and northern parts of the city are chiefly affected. Diphtheria shows 386 cases, as compared with 232 cases at the corresponding period last year.

#### EXTENSION OF EDINBURGH WOMEN'S HOSPITAL

An extension of the Hospital for Diseases of Women, at 2, 4, and 8, Archibald Place, Edinburgh, was opened on December 16th by the Duchess of Buccleuch. Mr T L Usher presided, and explained that the hospital had been opened in 1910 at No 2, Archibald Place, a house used by the late Dr Haultain as a private gynaecological home, and this had been bequeathed by him for the purposes of the hospital. The hospital had opened with fifteen beds. In 1912 the house at No 8 was added, and used for the accommodation of the nursing staff, and in 1926 the house at No 4 had been purchased, thus increasing the accommodation of the hospital to thirty-three beds. The patients paid a proportion of their maintenance, and in this way the home differed from a teaching hospital, where patients could go for nothing. Over 7,000 women had been treated and 1,600 major operations had been performed since the hospital began seventeen years ago.

### Correspondence.

#### MEMORIAL TO THE LATE PROFESSOR FRANCIS MITCHELL CAIRD

SIR,—A number of the friends of the late Mr Francis Mitchell Caird, a former lecturer on surgery in the Extra-Mural School and professor of clinical surgery in the University of Edinburgh, having expressed a desire to perpetuate his memory in the Edinburgh Medical School, a committee was appointed by the Medical Faculty of the University and the Council of the Royal College of Surgeons to consider what steps should be taken for this purpose.

The committee and the two bodies which it represented decided that the memorial should include a prize and medal open for competition to graduates of the University and Licentiates and Fellows of the Royal College of Surgeons of Edinburgh who have studied for two years in Edinburgh and have been qualified as practitioners for not more than seven years. The prize, offered biennially, will be awarded for the best essay in surgery or surgical pathology based on personal observation and research, the subject being chosen by the candidate.

Subscriptions of one guinea and upwards will be gratefully received. Those who have not been approached directly by the committee and are desirous of subscribing are invited to send their subscriptions by cheque or postal order, payable to the Francis Mitchell Caird Memorial Fund, per the accountant of the University and addressed to him at the University of Edinburgh, Old College, Edinburgh.—We are, etc.,

ALEXANDER MILLS,  
President Royal College of  
Surgeons of Edinburgh  
J LOBBAN SMITH,  
Dean of the Medical Faculty,  
University of Edinburgh

Edinburgh Dec 16th

#### TREATMENT OF PROSTATIC ENLARGEMENT

SIR,—I think it well to take exception to one (if not more) of the provocative statements made by Sir Cuthbert Wallace in the interesting Bradshaw Lecture published in the BRITISH MEDICAL JOURNAL of November 19th (p. 907). It is this that he says: "I am unaware, however, that a man has ever begotten a child after a prostatectomy."

Now patients who have undergone prostatectomy done by myself according to a method described in the BRITISH MEDICAL JOURNAL of October 3rd 1908, with illustrations, and in 1909, have begotten children. I well remember being startled by one of these patients during an evening visit to my private hospital, when he said, "I am afraid

<sup>1</sup> Nouvelle méthode de prostatectomie, 22nd Congrès de l'Association Française de Chirurgie.

something is going wrong with me, I had a wet dream this afternoon, a thing I have not had for nearly forty years." I administered a psycho-analyst's mixture with good effect. The question of paternity will, no doubt, be raised, but in one of my cases it can be solved by anthropological study of the offspring's features.

I had another patient (aged 60) who returned six months after operation to seek my advice about nocturnal emissions which worried him, because he had had no sexual desire for at least three years before operation. He promptly recovered after a mixture of heart to heart talk like unto the above.

I met this very brother old patient who is very proud of his second family from his third marriage.

I gave up private practice in July, 1914, but these cases have left fairly definite impressions about the relative merits of the two routes for attacking prostates. They may be worth relating as a contribution to the present controversy about the advice it is wisest to give.

I believe the safest course in most cases is to do this operation in two stages—that is, to do a preliminary suprapubic cystotomy, and let the patient get up as soon as he feels inclined to, then, when all is apparently going on well, to do the next and last stage by the combined suprapubic (already done) and perineal method referred to above.

Suprapubic cystotomy takes a short time to perform, and I agree with Sir Thomas Crues Evans's views on the assessable value of time in determining the rate of mortality after prostatectomy. Only this year, when visiting, with other members of the Chirurgical Club, a capital city in Europe, I happened to remark to a very distinguished foreign surgeon, while looking on at a suprapubic cystotomy being performed under a local anesthetic, that I had never seen perfect local anesthesia. The unexpected reply came, "You are quite right, I had the first stage of my prostatectomy done that way and I suffered lots of pain." He told me he was then wearing a muff. The next day I saw him do several abdominal operations in brilliant style, the second stage of his prostatectomy was going to be done after we left the capital for home, the delay was, I thought, sound.

The second stage of my operation, mentioned above, can be done in less time than any other method of prostatectomy finished it one sitting, because the perineal opening, in the second stage, can be made within one minute and the prostate is enucleated by the forefingers of both hands working simultaneously. Before enucleation is started I always filled the bladder with tincture of iodine so as to have a reliable antiseptic in contact with the new raw surfaces being formed.

It seems to me that success on the road to abolition of mortality will be found in the following factors, amongst others: (a) Preliminary psychic treatment of reassurance to the patient that he need not stop in bed, but can get up whenever he likes after operation. The dread of being bedridden is to old people a bog to be avoided. (b) Assurance that each stage of operation only takes a few minutes, and not hours or a big portion of one. (c) The operation to be performed in and through a harmless but efficient antiseptic—for example, tincture of iodine or 2 per cent mercuric iodine—I am, etc.,

Lechryd, Cuthbert hire Dec 13th

JOHN LEE THOMAS

SIR,—With reference to the statement that in the London hospitals a mortality of 40 per cent from the operation of prostatectomy has been experienced over a period of years, I think it is worth while to record that this mortality does not represent the average mortality throughout the country for this operation.

Taking my own private and hospital cases all together I have performed the suprapubic prostatectomy operation on thirty consecutive occasions with one death—a mortality of a fraction over 3 per cent. This includes several operations on malignant prostate.

It is evident that the mortality for selected cases will be very different from the mortality where many favourable cases are included and, of course, the subject

for operation in a country area are undoubtedly more favourable in constitution than those in a town area. At the same time, although the figures refer to a comparatively small number of cases, I think they dispose of Sir T. Carswell's contention that prostatectomy is an operation only to be performed by genito-urinary experts—I am, etc.,

Old Colwyn Dec 12th

A. NORMAN LEEMING

Sir—In your issue of December 10th (p. 1114) Sir T. Carswell alludes to the high mortality of suprapubic prostatectomy for which he is inclined to hold the general surgeon responsible. Thus, "so long as it is claimed that this operation is put off general surgery the mortality rate will remain where it is."

This is a formidable indictment based on a study of statistics from some general hospitals. Now the statistical approach to a surgical problem has its pitfalls. It is even possible to make too seriously some errors of statistics. For Sir T. Carswell uses the operation of prostatectomy as a "special" one beyond the compass of the average general surgeon—and I write as one. It demands he is told in his letter, a "particular knack or gift" and thus useful talent is the exclusive possession of the genito-urinary specialist. In his zeal for specialism I am afraid he has unduly stressed the difficulties of this operation. He will find little support for his argument in the address of the distinguished Bradshaw lecturer in November last who said removal of the adenomata is not a matter of delicate and difficult dissection but really consists in entering a line of cleavage already established and following it to its end. It matters little whether this is done under the eye or not."

So much then for the technique of the operation which after all it is only necessary to learn. A note is added on Freyer's pace in operating his dramatic mannerisms and low rate of mortality in a long series of cases. A fair inference would be that the bulk of them were adenomata capable of rapid enucleation by a dexterous surgeon. There cannot have been many examples of the small fibrous prostate in the series and reference to the case records in Freyer's book bears this out.

Several other points of interest arise in the letter. Operation by the open method is preferred to so-called "blind" prostatectomy. There are those who hold that either has its particular sphere of usefulness. For the simple adenomatous enlargement of the gland operation by the method popularized by Freyer has been found to suffice and has given good results in many hands. It is far other view in the small fibrous adenoid type of gland with little or no intracapsular projection. Here it is often hazardous to attempt enucleation and only by wide exposure of the bladder base and dissection under vision can removal be accomplished with safety. In every respect I have found this open operation a more severe procedure than enucleation, and reserve its employment for the cases of the fibrous type already referred to.

On the subject of after-treatment importance is attached to thorough irrigation as a means of maintaining the prostatic cavity clean. Unless the tube became blocked by clots I have always been averse to doing this, for I have found that irrigation tends to prolong oozing especially during the first few days after operation. In fact I have placed the cavity tightly with iodoform gauze, a method which I learned from E. S. Judd at the Mayo Clinic. The gauze serves a dual purpose. It promotes haemostasis and prevents stagnation of urine in the prostatic cavity. My practice is to loosen it up a little on the third day after operation and withdraw it entirely on the fourth when the tube is replaced—I am, etc.,

Winton Colwyn Dec 12th

GERALD RALPH

#### THE RAPID THERAPEUTIC ABORTION

Sir—The subject of therapeutic abortion ably discussed recently by Dr. Dalton in your correspondence column is one in which the honour and reputation of the profession are deeply concerned. Dr. Binnie Dunlop's definition of the term as "abortion performed by a medical practitioner or public medical—thatis, pathological—grounds" is a

point at issue. We need a detailed statement, acceptable to the majority of the medical profession, of what the words "pathological grounds" cover.

Dr. Binnie Dunlop's interpretation of them seems to be exceptionally wide. In the discussion on abortion in the Section of Obstetrics at the British Medical Association's Annual Meeting in 1926 the abstract of his speech contains the following sentence: "He considered it an indication of the desirability of this [that is, of terminating a pregnancy before the viability of the child] merely if the woman wished it, or rather if the woman could not be persuaded to desire the pregnancy to go on" (BRITISH MEDICAL JOURNAL vol. II, 1926, p. 247). In opening this discussion Dr. Edey mentions the barrister's wife on whom he after consultation with Dr. Herman, induced abortion merely because she objected to having a third baby shortly after the birth of a second. He also states that a consulting obstetrician procured an abortion for the same woman in her fourth pregnancy, and for the same reason. Later he gives details of a case in which he induced abortion because the woman was in a pitiable state of fear about the possibility of her death if the pregnancy (her third) went to full term.

In view of these openly expressed opinions by leading obstetricians I will state a case of common occurrence and ask a question.

An unmarried woman pregnant for the first time consults a string-lining medical practitioner in one of the poorer quarters of London. She tells him she is in a deadly state of fear if her pregnancy is allowed to go to full term. She feels she cannot face the anguish of the months that will elapse before her confinement nor the subsequent loss of employment and disgrace. If the doctor will not end her pregnancy she will try to do it herself and in so doing she feels she will go mad or she will commit suicide.

Now in this case is it the opinion of the majority of the medical profession that the doctor ought to induce abortion? If the answer is "Yes" then we as a profession are allowing, without protest, certain of our members to be criminally prosecuted and to be removed from the Register because they carry out a procedure which we consider correct and morally justified. If the answer is "No" then as a profession we are condoning a similar procedure if carried out by consulting obstetricians on wealthy and married patients. On which horn of the dilemma shall we impale our lives?—I am, etc.

London W 6 Dec 12th

C. TRACEY PAPSON

#### THE ABUSE OF CAESAREAN SECTION

Sir—Dr. Jellett was kind enough to refer to some statistics I had collected during a recent visit to America as a guest of the Rockefeller Foundation. Unfortunately it appears that America is not the only country where Caesarean section is popular. The abuse of Caesarean section may be classified under at least five headings.

1. As a method of treating eclampsia. In the year 1835 Dr. Collins as a result of his experience as Master of the Rotunda Hospital wrote as follows: "I would strongly caution junior practitioners to avoid hasty measures for the delivery of the child which perhaps alarm for the mother's safety might induce them to have recourse to." Although times have changed the word *recourse* is now as on the day they were written. Incidentally I may add that Dr. Collins's mortality rate for eclampsia was 16.0 per cent.

2. *Placenta praevia*. Holmes of Chicago gives the maternal and foetal mortality in placenta praevia treated by Caesarean section as 20 per cent and 30 per cent respectively while obstetrical treatment gave a mortality of 7 per cent and 55 per cent respectively. This according to him. Caesarean section saved one baby for every mother who was killed by the procedure.

3. *A ring for an experience*. Williams of Baltimore believes that in many places the mere diagnosis of contracted pelvis is regarded as an indication for Caesarean section irrespective of the fact that 75 to 80 per cent of cases of contracted pelvis will deliver themselves spontaneously if allowed to do so. In the Montreal Maternity

Hospital during the year 1923 there were 52 cases of contracted pelvis, but only 11 of these patients were delivered by Caesarean section

4 Its frequent performance is believed to add to the reputation of the operator (Williams)

5 Its mortality rate is considered trifling. The average mortality rate for this operation throughout the United States of America is believed to approach 10 per cent (Williams)

While passing no comment on the remedies that have been suggested, I beg to submit that a thorough ventilation of the limitations and the dangers of this operation may tend to make some practitioners less proud of the number of times they have performed it—I am, etc.,

Hon. Hong, Nov 5th

R E TOTTEHAM

#### SUSCEPTIBILITY TO INFECTION DURING PREGNANCY

SIR,—I would through your columns thank Dr C E Douglas for the booklet (containing much valuable and stimulating matter) which he has just sent to the doctors of Fife, but there is one paragraph with which I cannot agree—namely "We have in the pregnant woman a subject in which the immunity from disease and particularly from sepsis is not increased but diminished." I am sure Dr Douglas will agree that before accepting a deduction we must be sure of our premisses, and that the deduction logically follows therefrom.

A woman suffering from tuberculosis becomes pregnant. She remains well till her confinement." I quote Dr Douglas. This, in my opinion, is the premiss, and not what happens after parturition. Dr Douglas might have gone much further, and said that during pregnancy many tuberculous women very greatly improve. I have, for example, seen a tuberculous abscess completely dry up during pregnancy and in a month or two afterwards again become active.

My reason for writing is that I, too, have given much thought to this subject, my premiss being that there is in the pregnant woman's blood something which is antagonistic, certainly to tuberculosis, and probably to all microbial disease, and my deduction is, if we could find what this endocrine (for I presume it is such) is, we would be on the way to the discovery of a cure for tuberculosis. I have tried corpus luteum and thyroid, but without marked results. Still I am convinced that if the right substance could be found the results would be as I have stated. The pregnant woman's reaction to specific fevers bears out my contention. I agree that the parturient woman soon loses this immunity from disease, and may even reach a stage of less resistance than normal, but this does not affect the argument—I am, etc.,

A TAIT

#### CATARACT AND ULTRA-VIOLET LIGHT

SIR—Whilst flattered by Mr Duke-Elder's interest in my letter published in your issue of December 3rd, I feel that some of the conclusions he draws in his communication published in your issue of December 10th (p 1114) are unacceptable—any rate, by me.

Experiments on animals, especially on the excised eye of a rabbit supplied in normal physiological saline (which appears to be the only experiment Mr Duke-Elder has made on the eye with ultra-violet alone), are not convincing evidence that small, therapeutic doses of ultra-violet in conjunction with other luminous and infra-red rays are capable of producing cataract in the human eye. If so, may I ask him why he has advocated the use of ultra-violet radiation in the treatment of other diseases of the eye, both superficial and deep? Is he not of the opinion that, whilst he admittedly is curing these other inflammatory and infective disorders, he is not producing cataract? I feel quite assured that he has well satisfied himself upon this point.

Both he and Mr Bishop Haimm agree that ultra-violet light, in combination with strong luminous light, is capable of producing an intense conjunctivitis. Yet at least one of them would use ultra-violet in the treatment of the more chronic form of inflammatory diseases of the eye.

I can assure him that I have read with great interest

and profit his articles in the *Lancet* on the pathology of action of light upon the eye. In these articles he has admitted, and quotes an overwhelming mass of evidence to the effect, that luminous light and heat rays are well known to be causes of cataract. He states that "under experimental conditions opacity is difficult to obtain, owing to the difficulty of getting a sufficient amount of short waved radiation through the anterior eye. Further the lens proteins appear to be more stable under these radiations than most others. Several observers have therefore reported negative results." In his letter he states that "cataract is a coagulation of the proteins of the lens and proteins are coagulated by ultra-violet radiation." I agree—so are proteins coagulated, and much more readily, by heat. The chemistry of proteins covers an immense amount of literature, and is still far from complete.

What I suggest ultra-violet light may do, in therapeutic doses, is to arrest the pathological processes whereby normal proteins of the lens are being slowly converted into opaque coagulated material, and further permit Nature to remove some of the deposits via the lymph channel. If Mr Duke-Elder will read my original letter again he will see that nowhere do I suggest that radiation of any kind will "cure" cataract. When I wrote my first letter it was to prevent those who might read Mr Bishop Haimm's first communication being persuaded that ultra-violet light exerted a harmful effect in all conditions of the eye, and might, indeed, cause cataract.

I do not know whether the sting in the tail of Mr Duke-Elder's letter is especially intended for me. I would like to remind him, however, that but for enthusiasm and perseverance on the part of clinicians there would be no such things as "ascertained experimental data." Practically all the advances and discoveries in the history of medicine owe their inception to the enthusiasm and accurate powers of observation of practising clinicians, rather than to those who work in laboratories.

Nearly twenty years of constant practice in general medicine have not left me unable to make accurate observations, or liable to fail "to assess the complicated systemic influences which from time to time may alter the refractive properties of an unstable lens."

I have reported elsewhere two cases of cataract which I personally treated. Both had been under the care of ophthalmic surgeons of repute.

In one case after some two months' treatment with actinotherapy, the ophthalmic surgeon reported to me as follows: "There is no doubt that the vision has improved, as shown by the following: R V before was 6/12, now 6/9. L V before 6/9, now 6/6, and she herself thinks she is certainly better. Ophthalmic examination also shows some change which seems to me to be a thinning of the lens striae, so that the clearer intervals between them are wider."

In the other case, after twelve exposures spread over two months the patient—who had not been able to read the printed page for seven years, nor to distinguish faces—was able to read page 10 (Jaeger) with ease and to write letters in the train as well as to walk about the streets unaccompanied. The lady still has her cataracts but she has also got vastly improved vision.

There are possibly other cataract patients who might gain a like benefit. Certainly removal of the lens is not a "cure" for cataract, any more than amputation of the limb is a cure for an ankylosed knee-joint—I am, etc.,

London W Dec 10th

PERCY HALL

SIR,—It may interest some of your readers to hear that I had a patient with a slowly maturing cataract who had been to me for some years. A year ago he left me for some unqualified person's light treatment. I was somewhat surprised when he was led into my room by his son a fortnight ago. His vision was reduced to perception and perception of light only, in both eyes. He told me that he had been, and that it had cost him a hundred guineas, and asked me to operate on him which I did. He perfectly again, after refusing to stay longer in the hospital than a week.

Years ago Colonel H Herbert, now of Hong Kong, told me that in his opinion (he did some 20,000 lens extractions in India) cataract there was caused by the malarial fevers, possibly compounded with malnutrition in the native population—I am, etc.,

London W, Dec 15th

SIDNEY H.

## DII 1 AND PYORRHOEA

SIR—For the past few years I have been firmly convinced that diet is a most important factor in the causation of both dental caries and pyorrhoea, and have advised my patients accordingly, with varying results, depending on which the patient considered of greater value, 'the pleasures of the table' or 'the teeth'.

On January 20th 1927 Mr. X was referred to me by his medical adviser with the object of having several of his teeth extracted on account of pyorrhoea. He suffered from the typical so-called pyorrhoea with marked gingivitis and pus exuding on pressure from several points. Alveolar calculus was present in abundance on the lingual surfaces of the lower incisors and on the buccal surfaces of the upper molar teeth, and whitish was very marked. In the upper jaw were three teeth with ill fitting gold crown. A ray examination revealed general absorption of the alveolar margins but no apical infection. I removed the gold crowns, drained the pulp chambers, inserted creosote dressings and sealed with temporary cement being unwilling to proceed

I felt a ured that the condition was so treatment. At the same time I per- and instructed the patient in the proper care and hygiene of the mouth including the use of a mouth wash composed of lemon juice and water.

I reported the results of my examination to his doctor at the same time telling him that I thought it would be possible to save all the teeth if the patient could be persuaded to adopt a diet I should schedule for him. The doctor readily agreed to this and gave me wholehearted support which was of great assistance in tiding the patient over the difficult period that ran its course before any result could be seen or felt. The patient rather grudgingly agreed to give the treatment a trial for six months.

I prescribed a diet which contained a large proportion of fresh raw fruit and vegetable and of which the salient features were three meals daily—one fresh fruit one carbohydrate and one protein. The fresh fruit was eaten absolutely alone for breakfast the carbohydrate meal consisted of any kind of coarse grained bread with plenty of butter followed by a large raw vegetable salad and the protein meal consisted of a small portion of meat (to be taken not oftener than twice a week) or eggs or fish or cheese or poultry etc. always accompanied by two of the less starchy vegetables properly (that is conservatively) cooked and followed as in the carbohydrate meal by a large raw vegetable salad. I also allowed him when he desired to partake of a purely vegetable soup (neither bones nor meat or any kind to be used in its preparation) or stewed dried fruit. The carbohydrate and protein meals were to be taken one at mid-day and the other in the evening in whichever order the patient preferred. No condiments of any description were to be consumed.

The patient has reported at intervals since his first visit and an improvement has always been manifest. On November 14th, 1927 examination of his mouth revealed teeth firmly implanted in sockets, absence of pus pockets, no halitosis, no alveolar calculus and only the slightest traces of gingivitis which I am confident will disappear after a further period of treatment. The patient himself said that the rheumatism from which he had long suffered was quite gone and that constipation is much less marked. In appearance he looks much more virile his skin is clean and healthy and he declared voluntarily that his diet suited him admirably and that he would never think of returning to the old regime.

This result confirms what Howe McCollum Simmonds and others have been teaching—namely, that pyorrhoea is merely a symptom of a general poisoning of the body brought about by a wrong diet—I am etc.,

## TUBERCULOUS LESIONS FOLLOWING INJECTION OF PITUITARY EXTRACT

SIR—Would it not be as well to bear in mind the possibility that the cases noted by Messrs Donald and Lane-Roberts were due not to fresh infection by tubercle bacilli in the pituitary extract but to stirring up of an existing tuberculous focus in the patient, either by the injection or by the disease for which it was given?

In our urban population most people are infected with tubercle, though only a small proportion of these suffer from it, and the breakdown is nearly always due to quite other causes than the infection. That disturbance of endocrine balance is concerned is extremely probable though the connecting metabolic links between different accepted causes of tuberculosis have not yet been clearly traced—I am etc.,

## THE BIPP METHOD

SIR—With reference to the remarks of Professor Rutherford Morrison in your issue of December 16th (p 1077) on the "bipp method" of treating infected wounds, I think that one reason why this invaluable method is not more widely used is that many of the leading chemists sell under the name "bipp" an ointment with a base of soft paraffin (paraffinum molle) instead of the liquid paraffin. Such a preparation will not form a film on the surface of a wound and is therefore perfectly useless for the purpose intended—I am etc.,

## CONVEYANCE OF MILK

SIR—From your interesting note on the conveyance by rail of London's milk supply in glass-lined tanks (BRITISH MEDICAL JOURNAL, December 10th p 1102) it is not clear what precautions are taken to prevent contamination of the milk by mud and refuse from the churns when the churns emptied into the trough which leads to the coolers. I learn that in Denmark care is taken to avoid such contamination by not turning the churns upside down in emptying them and by rejecting the bottom layer of milk in which the grosser impurities accumulate. Moreover it is said that the milk is centrifugalized in order to remove muddy deposit. Perhaps the United Dairies Company would state whether any such methods are used in their process or whether reliance is placed on sterilizing the milk by pasteurization—I am, etc.,

## Universities and Colleges

## UNIVERSITY OF WALES

## Honorary Degree

At the last meeting of the Court of the University of Wales held at Colwyn Bay it was decided to confer the honorary degree of LL.D. upon Sir Thomas Lewis FRS for his distinguished scientific work in medicine particularly in cardiology upon Sir Robert Philip President of the British Medical Association for his distinguished services to the science and profession of medicine and upon Dr H B Brackeborn Chairman of Council of the British Medical Association for his distinguished services to the profession of medicine.

The actual Pro-Chancellor explained that the list of recipients of honorary degrees might not yet be complete since in view of the British Medical Association holding its annual Meeting in Cardiff next July it was contemplated that the University might like to confer degrees upon some eminent visitors attending the conference.

## UNIVERSITY OF OXFORD

THE Board of Management for the Francis and Taylor Memorial Prize in Physiology has awarded the prize to John Carey Eccles B.A. Magdalen M.B. B.S. Melb. who was recently elected to a Junior Research Fellowship at Exeter College.

At a congregation held on December 17th the following medical degrees were conferred:

MD—Subir J Eastwood  
BM—H A Bywater L W H Burt H P Gilding A W Cubi  
A P Kimbley R E Havard

## UNIVERSITY OF CAMBRIDGE

At a congregation held on December 19th the following medical degrees were conferred:

MD—D Laarus Barlow  
MB B Chm—G F Galden A S Hollis W S Grove  
By proxy

## UNIVERSITY OF LONDON

THE title of Emeritus Professor of Pathology in the University has been conferred on Sir Frederick Andrew OBE DCL MD FRCP LPS who retired from the University Professorship of Pathology, tenable at St Barholomew's Hospital Medical College in July 1927.

Lord Dawson of Penn has been appointed his representative of the University at the tercentenary celebrations in honour of William Harvey to be held in May 1928 at the Royal College of Physicians.

## Obituary

AMAND JULES McCONNELL ROUTH MD FRCP,  
Consulting Obstetric Physician Charing Cross Hospital and  
the Simultaneous Free Hospital for Women

We much regret to report the death, on December 15th of Dr Amand Routh, who rendered distinguished services to gynecology and took a great interest in the active campaign for the prevention of infantile mortality.

Amand Routh, who was the son of Dr C H Routh, a gynecologist well known in his day, was born in London in 1853. He was educated at King's College School and University College Hospital, he obtained the diplomas MRCS, LRCP in 1880, and graduated MB, BS and became MRCP in 1882. In 1882 he proceeded to 1900. During his student days he was captain of the Rugby football club of University College Hospital from 1875 to 1877, and for several years was a member of the United Hospitals football team. After practising for a little time in Upper Montagu Street he removed to Manchester Square, where he resided for nearly forty years, he also had a house and grounds close to the golf course at Northwood, which enabled him to devote himself to this game, of which he was no mean exponent. He was appointed pathologist and chloroformist at the Simultaneous Free Hospital for Women in 1881, he became out-

patient physician in 1882, and received charge of beds in 1884, being elected full physician soon afterwards. On his resignation in 1901 he was appointed consulting physician to the hospital. Dr Routh was elected obstetric physician to St Markham General Dispensary in 1882, consulting physician in 1890 and consulting obstetric physician to St John's Hospital, Twickenham, in the following year. From 1883 to 1893 he held the post of assistant physician in connection with Charing Cross Hospital, he then succeeded Dr Watt as obstetric physician and lecturer on midwifery. When he resigned in 1912 he was appointed consulting obstetric physician to the hospital. Soon after his appointment to the gynecological ward of Charing Cross Hospital he succeeded in getting the rule removed which prevented obstetric physicians from performing abdominal operations unless the patient was pregnant. He was examiner in midwifery and gynecology for the Conjoint Board from 1894 to 1900, for the University of London from 1901 to 1904 for the University of Birmingham from 1903 to 1906, and for the University of Cambridge from 1909 to 1915. He was on the standing committee of convocation of the University of London from 1904 to 1923, and a member of the Board of Advanced Medical Studies from 1906 to 1910. In 1910, on the invitation of the committee of the International Congress of Obstetrics and Gynecology at St Petersburg, he opened a discussion on Caesarean section. He attended this congress as representative of the Royal College of Physicians and Surgeons and of the Royal Society of Medicine. He published his report in a book entitled *Caesarean Section by Living Obstetricians in Great Britain and Ireland* (1911). This report, to which we refer at the time (JOURNAL, 1911 vol 1, p 219) led to much discussion and it was subsequently concluded that in most suitable cases when there had been no attempt at delivery the mortality of Caesarean section was only 10 to 12 per cent. Afterwards, however, the operation was employed in many unsuitable cases of eclampsia and parturition haemorrhage, and for minor pelvic contractures.

In 1917 he was elected president of the Hygienic Society, and his presidential address dealt with intestinal syphilis.

Dr Routh joined the British Medical Association in 1881 and about the same time was elected a fellow of the old Royal Medical-Chirurgical Society and of the Medical Society of London becoming a member of the councils of the two societies in 1902. He joined the original Obstetrical Society of London in 1882, and was a member of its council from 1886 to 1893, librarian from 1898 to 1900, secretary from 1900 to 1903, vice-president, 1904, and in 1911-13 was President of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine with which the old society had united. During his two years' presidency Dr Routh delivered presidential addresses emphasizing the need for advance in the chemical, physiological and pathological sides of menstruation, pregnancy, labour and lactation. One of these addresses was the basis of a leading article in our columns on 'The return to chemistry' (1911, vol. ii, p. 1118). Dr Routh also contributed to the volume on *Gynaecology* edited by Playfair (1894) for Allbutt's *System*, and published a large number of papers in various medical periodicals.

In 1912 Dr Routh joined the council of the National Association for the Prevention of Intestinal Mortality and persuaded this society to include in their scope the antenatal care of death and the need for medical supervision of pregnancy. In 1914 he delivered a lecture on antenatal hygiene and its influence on infantile mortality (*Journal*, 1914, vol. i, p. 355) which aroused considerable interest. It was estimated that the number of foetuses which perished was equivalent to the death rate in the first year in life, which was then about one in ten. Deputations to the Local Government Board followed and an important conference was held at the Guildhall. Dr Routh read another paper in April 1914 on the need for research in antenatal pathology, to which we referred in a leading article (1914, vol. i, p. 502). In the same year he gave evidence before the Royal Commission on Venereal Disease on the effect of syphilis on antenatal and infantile mortality and disease. The consequence of his strenuous advocacy was felt after the war when antenatal clinics were founded throughout the country and medical supervision during early pregnancy became increasingly popular.

Dr Routh was a strong opponent of artificial birth control except under medical advice and at the Church Congress at Leicester in 1919 he read a paper on the subject in which he advocated the two years' spacing of the birth of children by voluntary abstinence. He was churchwarden at St Paul's, Portman Square for nearly twenty years, and for several years was a member of the London Rural Medical and Middlesex Archdiocesan Conferences. He took a considerable interest in freemasonry from the year 1887 and obtained London Rank in 1910. He passed through the chairs of the Chere Rine (Charing Cross Hospital) Lodge which he founded in 1903 of the University of London (1905) of the William Harvey Chapter in 1915 and of the University of London Conclave or the Order of the Secret Monitor in 1918. After his retirement from active practice in September 1923 he removed to Folkestone and interested himself in local municipal affairs being elected a member of the borough council in November of that year.

Dr HENRY ERNEST KNIGHT to whose death we referred in our issue of December 10 (p. 1123) took a very active interest in the work of the British Medical Association in Rotherham. He was chairman of the Division from 1909 to 1925 and a member of the Executive and Editorial Committees from 1925 to 1926. Dr Stanley Wildman honorary secretary of the Rotherham Division, writes: It seemed scarcely credible that Dr Knight should have passed beyond, when it was remembered that precisely a week earlier he had been at dinner on November 25th. He had been his usual cheerful self. One cannot help feeling that with a smaller share of responsibility and a less warm devotion to duty he might have been still with us. Never was a man more devoted to the ideal and ambition of the British Medical Association. His sixteen years of chairmanship in the Division had afforded him a real knowledge

of all the difficulties that may be met as a medical man and his advice and example had always been helpful. It had been hoped that in the very near future he might have been elected chairman of the Yorkshire Branch. The Division and the profession of the district are the poorer for the loss of a kind, loyal and honoured brother. A remarkable tribute was paid to his memory at his funeral on December 5th. Rotherham Parish Church was crowded to its fullest capacity with a congregation representing the public and professional life of the district while thousands of the general public gathered outside to pay their respect. His loss will be greatly mourned especially by his professional brothers to whom he had always been ready and willing to give help or advice. The wreath which they sent to his funeral bore the inscription *With sorrow and remembering affection*.

Dr WILLIAM JOHN FRANKLIN CHURCHOTSE who died on December 5th, was born in 1855 and received his medical education at Charing Cross Hospital. In 1879 he obtained the diplomas L.S.A., L.R.C.P. Ed. and L.M. and four years later the I.R.C.P.S. Glasgow. He had held the posts of medical officer of health for the Daventry Urban and Rural Districts and had contributed two clinical notes to the *British Medical Journal*. He was a member of the Executive Committee of the Northamptonshire Division of the British Medical Association from 1923 to 1925, vice-chairman in 1924 and chairman from December 1924 to December 1925.

Dr MATTHEW THOMPSON, who died suddenly at his residence in Richmond on November 12th at the age of 56 received his medical education at St. Bartholomew's Hospital. In 1884 he obtained the diplomas M.P.C.S. Eng., L.R.C.P. Ed. and L.M. After holding the posts of house surgeon and house physician at the West London Hospital in 1886 he was attached to the Scots Guards as surgeon and accompanied Lord Wolseley's expedition to Khartoum. On his return he practised for a time in Lincolnshire and then removed to Hemel Hempstead, where he was appointed surgeon and later consulting surgeon to the West Hertfordshire Hospital. He took an active interest in local affairs, was mayor of Hemel Hempstead and a member of the Hertfordshire County Council. Dr Thompson was also chairman of the local Conservative Association and was selected as their candidate for Parliament but stood down in favour of an official nominee. At the beginning of the late war he received a commission in the R.A.M.C. and served at several home stations until 1919 when he retired to Richmond. He was a member of the British Medical Association. A colleague writes: As a striking example of Matthew Thompson's genius for friendship he for twenty years dined on May 27th with Bait's and Guy's friends made during student days. He will be much missed by many friends, and leaves a widow and two sons.

We regret to record the death on November 23rd of Dr GEORGE EDWARD MOORE of Maidenhead. He was born in 1857 received his early education at the South Grammar School and then proceeded to King's College. He took the diplomas of M.R.C.S. Eng. and L.R.C.P. Lond. in 1874 and graduated M.B. Lond. with honours in medicine in 1875. He was a keen athlete winning two half miles at the Inter Hospital Sport and playing Rugby football in the United Hospitals XV. On the formation of the Thames Valley Rugby Football Club he was elected its president. After serving as house-physician to King's College Hospital he joined as junior partner with Drs Richard Cooden and Playne at Maidenhead, where he continued to practise until his death. He was president of the Oxford and Reading Branch of the British Medical Association in 1885 and chairman of the Maidenhead Division in 1912-13. He took a great interest in educational work and was a governor of the County Boys' School for several years. He was chairman of the board of governors of the Maidenhead Hospital. Dr Moore's made a justice of the peace for the borough in 1924. His

son, Lieutenant R. L. Moore of the Somerset Light Infantry, was killed in 1914. Another son is Dr. Gilbert Moore, M.C., who was in practice with his father.

Dr. JOHN EALEY died on December 8th, aged 62. He was educated at Yorkshire College, Leeds, and took the diplomas of L.R.C.P. in 1887 and M.R.C.S. Eng. in 1888. Early in his professional career he acquired the practice of Dr. Hick of New Wortley, and had remained in the district ever since. He was medical officer of the Leeds Prison, Armley, for twenty-five years. He resigned the post of district medical officer for Wortley in August, 1926, which he had held for thirty-seven years. In 1920 he was elected a member of the city council, and represented the New Wortley Ward for three years. In 1924 he was appointed a justice of the peace. He is survived by his widow, one son (Dr. Cyril J. G. Ealey), and one daughter. At the sitting of the Leeds Police Com. on December 8th sympathetic reference was made to Dr. Ealey's death from the bench, and by the chief constable and members of the legal profession.

Dr. CHARLES MACARTHUR ARLEN of Longton, who died on December 12th, was a member of an old Highland family and was born at Strathspey 67 years ago. He received his early education at Granton and Old Aberdeen Grammar Schools, and studied later at the University of Edinburgh. He graduated M.A. in 1882, M.B., C.M. Edin. in 1887, and proceeded M.D. ten years later. He commenced practice in Longton in 1888 in partnership with the late Dr. James Grant, on whose death he succeeded to the practice. He took great interest in ambulance work, and in recognition of his services was appointed an honorary life member of the Order of St. John of Jerusalem. He was public vaccinator for Longton and formerly school medical officer, and had served as a member, vice-chairman, and chairman of the Longton Education Committee. Dr. Allan was president of the North Staffordshire Medical Society for 1923-24, and was a member of the North Staffordshire Division of the British Medical Association. He had been president of the Men's Golf Club since its inception in 1889.

Dr. WILLIAM GIBB DUN, who died on December 10th, in his 78th year, received his medical education at Glasgow, where he graduated M.B., C.M. with commendation in 1877, and proceeded M.D. three years later. He became F.R.F.P.S. Glas. in 1881. After holding the post of house-surgeon at the Royal and Western Infirmarys he was appointed assistant to the professor of clinical medicine in the University of Glasgow in 1881. For many years he was assistant physician to the Western Infirmary and physician to the Society for the Prevention of Cinelty to Children. He was an ex-President of the Royal Faculty of Physicians and Surgeons of Glasgow of which he was for some years treasurer, and was president of the Glasgow Medico-Chirurgical Society.

Dr. JOSEPH McGRATH, who died on November 11th at the age of 59, received his medical education at Queen's College Belfast, and graduated M.B., B.Ch., B.A.O. of the Royal University of Ireland in 1893. He served during the war in the Tank Corps. He had practised for several years in South Kensington, and was a member of the British Medical Association.

In a footnote to his paper in our issue of December 3rd (p. 1019) we had to announce with regret the death in his sixtieth year, of Dr. JULIUS PETERSEN, professor of medicine in the University of Lund. He was a well known writer on renal and tuberculous subjects, especially diabetes, nephritis and international congresses and a few months before his death which occurred from cerebral hemorrhage on October 15th, he took part in the discussion

on epidemic encephalitis in the Section of Nervous and Mental Diseases, and read a paper on the statistical evidence of the value of insulin in the Section of Medicine at the Annual Meeting of the British Medical Association at Edinburgh last July. A sympathetic memoir by Professor Knud Faber of Copenhagen, with portrait, appears in the issue of *Hospitalstidende* for October 20th.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

BOTH Houses of Parliament were busy this week in hurrying bills through their closing stages to be ready for the Royal Assent which was arranged to be given on Thursday when the session was due to close. The House of Commons also debated unemployment and the state of British agriculture. No official information was available on the Government programme of business for next session, but a Factory Bill is still anticipated and a suggestion has been heard during the week that the Government may introduce in 1928 a National Health Insurance Bill based on the recommendations of the Royal Commission.

### Medical and Dentists Acts Amendment Bill

*The G. V. C. and the Irish Free State*  
In the House of Commons, on December 16th Sir Kinnaird Wood moved the second reading of the Medical and Dentists Acts Amendment Bill, embodying an agreement between the Irish Free State and the United Kingdom consequent on the establishment of the Free State and legislation which had followed by it, he said, the General Medical Council had to exercise its authority on control over the medical profession in the Irish Free State, and had ceased also to be able to place on its Register students who had obtained medical qualifications in the Irish Free State. Both sides regarded the position as unsatisfactory and had been negotiating. By an interim arrangement the General Medical Council agreed to accept for the United Kingdom Register students with qualifications obtained in the Free State. To validate that agreement was one of the objects of the bill. A signed agreement set out this year and had the concurrence and support of the General Medical Council. The Government had been assisted in the matter by Sir Donald MacAlister, president of the Council. Under the agreement the Council would continue to admit to the Medical Register all persons who, prior to the establishment of the Irish Free State, would have been admissible in respect of qualifications there obtained. The Council would possess the right to such admission so far as was necessary for keeping the United Kingdom Register and would have complete control of that Register and of the profession in the Irish Free State. The bill provided for admission to that Register on equal terms of all persons on the United Kingdom Register. The position with regard to the Dentists Act was similar, and was embodied in Part II of the schedule. The Government had been assisted by Sir Francis Ashford, chairman of the Dental Board of the United Kingdom. The Free State had passed legislation to give effect to the medical side of the agreement in the Irish Free State where two bills were required. He thought the bill before the House was a happy solution of the difficulties which had arisen. The House read the bill a second time without opposition.

### Nursing Homes Registration Bill

On December 16th the House of Commons considered the Nursing Homes (Registration) Bill as reported with amendments for Committee. Captain Cazalet moved a new clause as follows:

1. Under of Minister to Exempt Christian Science Nurses from this Act in respect of any nursing home as respects which it is that it is a nursing home, or will be carried on in accordance with the principles of the body known as the Church of Christ Scientist.
- (2) It shall be a condition of an exemption granted to a nursing home that the nursing home shall adopt and use the Christian Science nursing home.
- (3) An exemption granted under this section in respect of a nursing home may at any time be withdrawn by the Minister if it is found that the nursing home is not being carried on in accordance with the principles of the body known as the Church of Christ Scientist.

Captain Cazalet said the bill as received from Committee would compel any nursing home to have in charge a qualified medical practitioner or a qualified nurse. He thought the bill was a happy solution of the difficulties which had arisen. The House read the bill a second time without opposition.

entirely different from that of the medical profession and a qualified medical man or qualified nurse must disapprove of the methods adopted in Christian Science homes. Captain Cazale explained that these homes, of which there were thirty in England and Wales, did not take maternity cases requiring surgical operation or cases of infectious diseases. No attempt was made under the proposed new clause to exclude any of the rules and regulations on ventilation, sanitation and such matters. The homes were prepared to submit to any inspection and registration thought desirable by the Ministry of Health and he understood the new clause conformed with the requirements of the Ministry. Viscountess A. for seconded the proposed clause. Sir Cyril Cobb who had been chairman of the Select Committee on Nursing Homes said that committee held on the evidence which came before them that there should be no exemptions for institutions in the nature of nursing homes where payment was made. They had been told among other things that the General Medical Council would ensure that homes kept by medical men where they received patients for fee were properly run and that they need not fear such homes would not be provided with trained nurses. But evidence showed some of the worst cases of neglect occurred in nursing homes which were run by doctors. On the proposed clause they were not dealing with a religious question but a medical and nursing question. Though a small exemption had been made in the bill for existing nursing homes the evidence had been conclusive that a nursing home should have qualified nurses on its staff even if it did not have at the moment a qualified nurse or a qualified medical man at its head. He must vote against the clause which according to Sir Kingsley Wood's words in Committee would drive a home and coach through the bill. Mr Morris asked how the Minister of Health would be kept informed of any modification of Christian Science doctrine, practice and principles. Lady A. for They do not change.

Sir Richard Luce, a member of the Select Committee on Nursing Homes, opposed the clause. He said the Committee had received two applications for exemption of nursing home one from member of the medical profession and the other from representatives of the Christian Science Church. It became evident that it was unwise to grant exemption for homes under the charge of medical men and it would be unfair to give exemption to any other body which claimed it on much the same grounds. Before the Select Committee the representative of the Christian Science Church had said there were only three Christian Science nursing homes in the country located in places in the nature of boarding houses where patients could go to a treatment. Now Captain Cazale said there were thirty or forty Christian Science nursing homes. If the boarding houses were now being included there would not come under the name of nursing home and there would be no great hardship in closing down the few which were definitely nursing homes. The clause did not seem to guarantee that the homes it proposed to exempt would be properly inspected. The Minister was not to take the responsibility of inspecting them and the guarantee that they belonged to a particular Church did not give any guarantee that the homes were being run on proper lines. Other unorthodox methods of treatment were in vogue in this country. How could the Minister of Health in future refuse exemption to these also set up homes? He opposed the House would not agree to the clause.

Mr Chamberlain and he was not a Christian Scientist. So far as the practice of Christian Science was to substitute other methods or medical and surgical and he disapproved of it. The House was not concerned with doctrines but to see that no member of the public was deceived and Christian Science was not carried out as medical treatment there was no pretence that treatment which was given by Christian Scientists was offered as an alternative to medical treatment or as a variety of medical treatment. If by bringing these points under the bill the House required them to appoint a qualified nurse as superintendent who would be a piece of camouflage introduced so that they could be said to be nursing homes and would be likely to deceive the public. Members were unwise to attempt to bring these homes under the bill.

Dr V. Davies intervening said the bill referred to nursing homes. If the Christian Scientists referred to their homes as homes of rest or homes of treatment they would not come under the bill and the public would not be deceived.

Mr Chamberlain and he was advised that such institutions would come within the definition of nursing homes in the bill. To say that the practices of Christian Science should not be carried on in an institution though legal elsewhere would be regarded as persecution of religious opinion. The inclusion of these institutions under the bill offered difficulties so serious that he could not contemplate it. The main consideration was to see that the public if it entered one of these institutions did so with its eyes open. His object would be secured if they could get some test whereby the institutions could be separated from homes set up by unqualified persons posing as medical practitioners. Captain Cazale's clause carried out his idea in that the homes were to be called nursing homes. Mr Chamberlain suggested that Captain Cazale should use some other title such as Christian Science house which did not involve any suggestion of medical practice. The public could not read the Act they would read the title put up on the door of the institution. Mr Montague suggested Christian Science home. Mr Chamberlain said that even the word home suggested something in the nature of nursing home.

Mr Thomas said the Minister had made it clear that no body whether Christian Scientists or otherwise could come to the House with the hope it would co-operate in right to an institution to say "No matter what we do no matter what a practice we are engaged in or in a profession. The House would not be in any way such claim. Captain Cazale said the responsibility for the new clause was resting on a point my name which I submit might suggest and the House approve.

Dr Fremantle asked the House to recognize that it was the position of medical men called to make such an exemption. These were not questions of kindred humanity charity or liberty. They were concerned with the protection of the public. He saw nothing about the homes to which exemption was claimed nor did the Minister of Health. He understood there was no body in this country representing the Christian Science faith which could certify these homes. If they were rest homes they would attract people who had disease and to know whether they were nursing homes or not would become practically impossible. The more ignorant portion of the public did not know the difference between Christian Science and any other science. If the House opened the door to this could they prevent it opening to the older and more widespread cult of homeopathy or to the osteopaths? He wondered how the Minister was to have the knowledge which would make it appear to him that the exemptions were not being properly carried out. Would the Minister and his officers have the right to inspect? He could not vote for this clause without further assurances.

Mr Gerald Hurd said he had come to oppose the clause but he thought the courses open made by Captain Cazale removed all suspicions and distrust. He suggested drafting amendments including the name of the word institution at certain passages in the bill.

Dr V. Davies thought the alteration of the word home to house got over much difficulty. He could not associate himself fully with Dr Fremantle. If it was necessary that homes or houses should be provided for the particular treatment of Christian Science then people had a right to go to them and neither medical men nor members of Parliament had a right to interfere provided the public were safeguarded and were not being deceived. It would be impossible for a person of adult age to go into a Christian Science house in ignorance. Whether when there he would be well or ill treated was no concern of the community. He suggested that the Minister to be satisfied that the house was carried on in accordance with the principles of the body known as the Church of Christ Scientist should require the head of that church in this country to certify that it was one of their houses carried on according to their principles. Sir Kingsley Wood said the head of the church would give the certificate. Miss Wilkinson remarked that there was no more profitable way of making money in this country than having some way of curing people which was different from anything previously advocated. Would the houses be situated and by someone in this country or in Boston. Sir Kingsley Wood said the head of the church in this country was well known and would be recognized by the Ministry. Captain Cazale said new clause was then read a second time and with the substitution of "house" for "nursing home" added to the bill.

On Clause 5 (Inspection of Nursing Homes) Mr Gerald Hurd moved to insert "qualified nurse or" in page 4 line 37 after the word "one" to emphasize that when the medical officer of health deputized some official to inspect and visit nursing homes he should bear in mind that the official primarily qualified would deal with questions of nursing while a qualified nurse Miss Wilkinson seconded and applied for a qualified nurse to be the back premises and the nursing side. She knew instances of epileptic and dirty material was stored in the kitchen or in the bathroom. A busy practitioner could not go into such details they were jobs for nurses. The amendment was agreed to.

On Clause 8 (Local supervising authority) Mr Chamberlain moved to insert as the authority "the council of each county as respects that county and the council of every county borough as respects that borough." He said the Standing Committee before which the bill came had decided that a district committee whose medical officer was not otherwise employed might also act. Since the proceedings in Committee representatives of the various classes of local authority had agreed on the amendment which was included in his name. This amendment went back to the original county borough or county council as the supervising authority but powers were given to the authority to delegate its powers to a minor authority and the minor authority had the right to apply along to the Minister if their application for such delegation were refused. Mr Paine said the compromise had been reached without authority from the County Councils. On occasion Dr Fremantle said that that association chairman had power to act. Dr Fremantle said that certain that to have the inspection entirely to county councils and county borough council was best as had been done in the Maternity Homes Act but friends of the bill had the alternative of doing it or of accepting the compromise. With great hesitation he asked them to accept the compromise and asked the Minister to see that the bodies to whom the powers were delegated used them in the interests of the public. Miss Wilkinson condemned what she thought a thoroughly retrograde step. She had resolutions from the National Council of Nurses against it being carried on by these smaller bodies. Colonel Appin asked for assurance that the midwife would not be under the authority of Mr Viant said a number of urban districts had their own medical officers. Mr Chamberlain said he would not put his name to such a compromise even to secure the bill unless convinced it was a good one and would work out in practice. The next amendment with reference to delegation said

The council of a county may, on the application of the council of any county district within the county, delegate to the council of that district or to any sub-committee, or to any committee, or to any other body, such powers as it may think fit in relation to the powers or duties of the council of that district under this Act.

He felt certain these words would avoid the duplication of inspection. Where a minor body had a committee staff undertaking work in connection with prenatal conditions a county council might delegate the inspection of maternity homes to them and say

Will you take from us the inspection of midwives and act as our agents? It would be possible to make arrangements of that kind. Miss Wilson asked whether the effect of what the Minister had said was to make it possible for the county council to hand

over to the smaller authorities the supervision of midwives, which they could not do under the terms of the Maternity Homes Act. Mr Chamberlain said the county council could not delegate responsibility. They might make arrangements for the inspection to be carried out by the officers of another authority, if that authority cared to lend them for the purpose. If was not a question of the delegation of responsibility, but merely a question of the particular individual who would make the inspection.

The first amendment restoring the powers of inspection to the councils and county borough councils was carried by a vote of 10 to 4, which also added the metropolitan councils to the list of authorities above by Mr Chamberlain.

The first amendment would make the inspection of the district council and county borough councils which also added the amendment restoring the powers of inspection to county councils and county borough councils was then made by the House, above by Mr Chamberlain), and a further subsection declaring that if any district council by which an application is made under sub section (2) of this section is aggrieved by the refusal of the House, council to delegate any of its powers or duties otherwise than subject to restrictions, the district council may make a representation to the Minister with respect to the matter, and the Minister, after consultation with the county council, may direct the county council to delegate to the district council, either with or without restrictions or conditions, such of its powers and duties under this Act as the Minister thinks proper, and the county council shall comply with any direction so given.

After adding consequential amendments on the payment of expenses the House reported the bill and, on the motion of Mrs. Philipson, it was read a third time.

Viscount Gage moved the second reading of the bill, and the bill was read a second time.

(Registration) Bill in the House of Lords.

Lord Dawson of Penn said:

The bill among other things

Lord Dawson of Penn said there was not universal agreement among the laity and the professional body as to the necessity of the bill to carry out its provisions.

the bill among the House of Lords on December 20th. I have to carry out its provisions. The sole justification for the bill was that the report of the professional men who would have considered the matter disclosed very serious abuses which had gathered round certain nursing homes in various parts of the country. The public were being exploited and he thought that anyone who had studied that report sufficiently must recognize that there were abuses which would justify action on the part of the Government. So far as the improvement of nursing homes from a professional point of view was concerned he was very sceptical as to whether it was possible to improve them by any system of inspection. The real way to secure improvement was to set up proper institutions and buildings for the care of the sick. In so far as they did that the more inefficient nursing homes would cease to exist. The bill gave powers of a most extraordinary character, and those powers should be used well. He thought that they might lead to intolerable abuses if they were not used with the utmost care. He thought that the bill was a most important one.

the real way to improve them was very proper institutions and buildings for any sick In so far as they did that the more they would cease to exist The bill gave powers of the character, and those powers should be used with great discretion, or they might lead to intolerable tyranny. He feared that there might arise a pettifogging type of inspector, who would do more harm than good. One incidental effect of legislation of this kind would be that they would put the medical profession of this kind local authorities, and the more they did that the more would they make for the municipalization of medicine in this country. Ho could understand people who were in favour of a State medical service voting for this bill. He was strongly in favour of setting up some sort of committee which would correspond to the committee set up by the education authority. That Committee would deal with the health services and would bring the official and unofficial sections together. The real case for the bill was that it would prevent the abuses that were disclosed before the Select Committee. Ho would therefore support the bill. Earl Russell criticized the clause dealing with the homes, and protested against the clause dealing with the Marquess of Salisbury.

The bill was read a second time

*Mental Deficiency Bill*  
The Mental Deficiency Bill was read a first time in the House of Lords on December 16th and passed through Committee without amendment on December 20th

*Landlord and Tenant Bill Compensation for Improvements*

During the Committee stage of the Landlord and Tenant Bill in the House of Lords on December 16th, the Duke of Northumberland moved to amend the subsection of the bill which provided that in claims for improvements made by leaseholders premises used for carrying on a profession shall be deemed to be premises used for carrying on a trade or business. He proposed to insert the words 'A profession for the purpose of this section means the habitual and regular practice of a learned or skilled profession as the chief means of livelihood.' He said the object of adding 'professions' in the section was that the Act should apply to learned and scientific professions which were essential to any civilized society to doctors, dentists and so forth. Lord Sumner said a person who practised the subordinate arts of healing—the man who took x-ray photographs was a good instance—would not be regarded as a tradesman and would not be called a business man but to what profession did he belong? He supported the amendment. The Lord Chancellor said the framers of the section intended to meet the case of a doctor who wished to add a surgery to the house where if at the end of the term some value remained to the landlord the tenant should have compensation for the unexhausted value. The professional man had no right in the Duke of Northumberland would raise difficulties. If at the beginning a doctor got little profit from his profession, should he for this reason be cut off from compensation if having found the money for the surgery he lost it? To meet the point raised by

*National Health Insurance*—At a rough approximation Mr Chamberlain estimates that some 14,000,000 persons insured in England and Wales under the Health Insurance Act lost upwards of 150,000 000 working days from sickness in 1925, and upwards of 169,000 000 working days in 1926. No data are available on days lost through sickness in the general population.

*Health of Troops in China*—Introductory statement by the Hon. the Commander-in-Chief, India, on the supplementary estimate of 1927-28.

*Health of Troops in China*—Introducing, on December 14th a supplementary estimate of £3,090,000 for British troops in China, Commander Douglas King, Financial Secretary to the War Office, said that the troops at Shanghai had been in a confined space with improvised encampments and restricted facilities for recreation. Their health, in view of these circumstances, had been very satisfactory. During the early months of the occupation there had been a serious outbreak of pneumonia, attributed to the climatic conditions and to the common habit of the Chinese of spitting on the ground everywhere, in public carriages, and all public places. Mr. Trevelyan, in an attempt to learn the average amount of sickness among the British troops in China, said he was never able to get any definite information as to the number out there. He would assume that there was an average of 20,000 during this year. According to figures supplied, the approximate number in hospital in March was 580, in April 710, in May 870, in June 959, in July 1,309, in August 1,132, in September 1,191, in October 799, and in November 713. These figures showed that there were always something like one in twenty in hospital. He did not think that was a very good average. Mr. Welles drew attention to the statement in a medical newspaper that the rate of venereal disease among the British troops at Shanghai had been high and had given the command much anxiety. Many tragedies would follow what an eminent doctor who had been out to China stated to have taken place. The estimate was carried.

*Small pox*—The Home Secretary states that 1,000 notified in prisons of England, Scotland, and Wales, in the month of December 12th 1927, eight small pox cases.

*Small pox*.—The Home Secretary states that during the year ended December 12th 1927, eight cases of small pox had been notified in prisons of England and Wales. Prisoners suffering from small pox were removed at once to hospitals for infectious diseases. The Minister of Health has no previous information on the cost of recent outbreaks of small pox. This cost is met from local funds. In an answer to Mr. Groves on December 15th Mr. Chamberlain said forty five cases of small pox recently occurred in Newcastle on Tyne Poor Law institution. Forty two patients, whose ages ranged from 17 to 70 years had been vaccinated in infancy only one had been re-vaccinated ten years ago. Before the outbreak there had been no general vaccination of the inmates for fifteen years. Inmates recently vaccinated and re-vaccinated had been attacked by small pox, but in no case had the vaccination been successful.

*Hospitals and Hospital Beds*.—Early in 1925 the number of State hospitals and

*Hospitals and Hospital Beds.*—Earl Winterton states that in 1925 the number of State public local fund, and private ind. hospitals and dispensaries in British India was 3,972 and the number of beds available 45,049. The number of indoor and outdoor patients treated was 738,570 and 40,472,780 respectively. The number of female hospitals and dispensaries was 173, with 4,249 beds available. The number of beds available for women in general hospitals was 11,260.

*Treatment by Sunlight and Sea.*—The number of patients treated at the Commander Kenworthy's Sanatorium, Scarborough, in 1925 was 1,000.

*Treatment by Sunlight and Vapour Baths*—In an answer to  
Commander Kenworthy Mr Chamberlain said he had visited the  
sunlight and vapour baths of the Hull Corporation and regarded  
them as a valuable experiment but they had not been long  
enough in existence for him to recommend a similar system to  
other municipalities. Answering Mr Hardie Mr Chamberlain said  
he did not propose the introduction of legislation to control by  
establishments for treatment by ultra violet rays and other  
radiations

*Prescription of Alcohol*—Answering Mr Macquisten on December 15th, Mr A M Samuel said it would not be practicable to exempt from duty spirits consumed on the advice of doctors. The law provided for a rebate of about four fifths of the duty on spirits in recognized medical preparations. If spirituous preparations needed to be prescribed medicinally for spiritual purposes, the cost fell on the drug fund, and there was no question of personal hardship to deter panel doctors from prescribing. Mr Macquisten in his question alleged that brandy and other doctors frequently prescribed the use of spirits in influenza and pneumonia. I suggested that in all such cases panel doctors frequently position to supply patients with duty free spirits for medicinal purposes. He offered to give instances where consumers who were lifelong abstainers had been ordered by their doctors to consume spirits medicinally.

**Nutritive Value of Skimmed Milk**—Sir Kingsley Wood states that rather more of the nutritive constituents of milk than fat can be obtained for one penny from condensed skimmed milk than from ordinary milk. It is far cheaper, and considerably more is supplied by condensed skimmed milk over and to the sugar which it contains. Its nutritive value is concerned which amounts to about 0.5 per cent renders this milk unsuitable for infants.

**Food and Drugs Acts**—Dr Davies asked Mr. Clarendon whether he would give in traction that in future the authorities administering the Sale of Food and Drugs Acts should co-ordinate their activities upon taking more samples of the foods and

the poor rich is polonic in its and potted meat Mr Chamberlain said he was not empowered to instruct local authorities who could not continue their attention to selected article

**Blind Persons.**—The cost of maintaining the Blind Persons Act 1920 in England and Wales amount to about £200,000 a year. This is exclusive of the large amounts paid by voluntary agencies for the purpose of the Act and of the contribution made by the Free School and the local education authorities for education and training of the blind. The number of registered blind persons in England and Wales on March 31st 1921 was 46,822. Of these there were 17,252 between the ages of 50 and 70.

#### Votes in Brief

The Minister of Health will shortly publish figures giving particulars of the results of various schemes for the treatment of tuberculosis.

The Committee on Vaccination has met thirty times, and Mr Chamberlain states that it is now considering its report.

## Medical News.

THE foundation stone of the extension building of the Elizabeth Garrett Anderson Hospital, Euston Road, London, was laid on December 15th by Sir Alan Garrett Anderson, B.E., the son of the founder.

THE Royal College of Physicians of London will be closed from to-day, Friday, December 23rd, to Saturday, December 31st, both days inclusive.

THE meeting of the St John's Hospital Dermatological Society arranged for December 28th has been cancelled. The next meeting will be held at St John's Hospital, 49 Leicester Square, W.C. on Wednesday, January 25th 1923. The annual oration before the society will be delivered by Sir John Bland Sutton, Bt, on May 23rd, the subject being the debt of dermatology to optical glass.

AT the meeting of the Tuberculosis Society on Friday, January 20th, there will be a discussion on the work and aims of tuberculosis care committees and industrial agencies. At this meeting, which will take place at 8 p.m. at the house of the Royal Society of Medicine (1, Wimpole Street, W.), the draft constitution and by-laws of the Tuberculosis Association will be submitted.

AN illustrated lecture on modern athletics will be given by Mr H. M. Abrahamson at the Central Hall, Westminster, on January 13th 1923, at 3 p.m., in aid of the Tavistock Clinic for Functional Nervous Disorders.

THE Royal Institution has now issued its programme of lectures to be given before Easter. Among the Friday evening discourses will be one (on March 2nd) on the psychology of the sick, by Sir Farquhar Buzzard, the new Peckham Professor of Medicine at Oxford, and another by the daughter of his predecessor, Miss D. A. Garrod, on prebiotic cave art. The discourse on February 3rd will be by Professor E. C. C. Baly on photosynthesis and that on February 17th by the Rev. Dr. E. M. Walker on the university, its ideals and its problems. The juvenile Christmas lectures this year will be given by Professor Andrade, who will tell his hearers about engines. Among the general courses of lectures will be one on the physiological aspects of flying by Group Captain Martin Flack, Director of Medical Research, R.A.F.M.S., on March 22nd and 29th at 5.15.

THE report presented to the annual meeting of the constituents of the Metropolitan Hospital Sunday Fund held at the Mansion House on December 19th, showed that the collections this year amounted to £56,935.

VISCOUNT KNOTSFORD presided at the annual meeting of the British Charities Association held at Kingsway House, London, on December 15th. He reported that the activities of the association had resulted in a surplus for the year of £18,120, being an increase of over £4,000 on the previous year's figure. Distributions to voluntary hospitals during the year amounted to £20,600, and the council had since made further grants of £15,000 to King Edward's Hospital Fund for London and £5,000 to the League of Mercy, the latter for distribution among hospitals outside the London area. The total distributions since the formation of the association four years ago now exceed £173,000.

THE first annual dinner of the Ringer Society was held on December 10th at Jules Restaurant with Dr Henry Ellis in the chair. A large company of guests were present at the invitation of the president and council. The president delivered the Ringer Oration. He explained that the society was named after Sydney Ringer, one of the first clinicians to realize the value of physiology and biochemistry applied to practical medicine and best remembered perhaps by his perfusion experiments with the fluid bearing, his name. Dr Ellis explained that the council of the society

had been actively engaged in formulating standards of urinary analysis and as a result of team work among different members of the council, working independently, these had been almost completed. He stated that the society would, in the ensuing year, proceed to define standards for blood in the same way. Professor Maclean, in response to the toast of Clinical Biochemistry, said he was much interested in the evidence presented of the activities of the society, and Professor Joseph Barcroft of Cambridge also replied. The health of the guests was proposed by Dr Halli, Bally, who said that one of the aims of the society was to study functional efficiency and Dr Langdon Brown and C. F. V. O., who replied, spoke optimistically as to the future of biochemistry applied clinically in the way advocated by the society. The health of the president was proposed by Dr David Barcroft.

THE KING has appointed Dr Joseph Clarke McLerron, senior medical officer to be an official member of the Executive Council of the Presidency of Montserrat.

DR A. R. WIGHT, who has been elected provost of the bursar of Leslie, has been a member of the Town Council since 1905 with a break of only three years during that period. He graduated M.B. Ch.B. in 1897 and is a member of the British Medical Association and the Lincolns Medical Association.

DR FREDERICK CHARLES WILLMOT, Government Health Department, Capetown, South Africa, has been elected a Fellow of the Royal Sanitary Institute.

THE Mental After-Care Association for poor persons convalescent or recovered from institutions for the insane is appealing for funds to continue and extend its work. One of its chief objects is the prevention of relapse, and last year 1,650 persons were assisted. Contributions should be sent to the secretary, Miss Vickers, Church House, Deans Yard, Westminster S.W.1.

THE Minister of Health has issued a revision of a memorandum which was first published in March 1921 and dealt with the provision of treatment for tuberculous excretors. In the revised memorandum—30/T (Revised)—it is announced that certain modifications will be introduced on January 1st 1923. County and county borough councils are now asked to prepare and authoritative lists of patients whose treatment is chargeable to the Ministry of Pensions, thus correcting the present lists which, owing to the lapse of time, have become inaccurate. The Ministry of Pensions will continue to notify councils of any fresh cases which from time to time are accepted for financial support by the Ministry. Tuberculosis officers are warned that treatment allowances are not necessarily payable when a man is incapacitated by his war disablement but only in those cases now much reduced in number where a special treatment is to be undertaken precludes the man from following his usual occupation. A list of the addresses of the chief area officers accompanies the circular which has been sent to county councils, county borough councils, and tuberculosis joint committees of England.

By her will the late Mrs. Maryat has directed that, after paying public bequests amounting to £380,000, the residue of her estate is to be divided into two parts, one of which is to be paid to the governors of the Dundee Royal Infirmary to be funded for the purpose of that institution and the Sidlaw Sanatorium. It is understood that the sum to be funded will yield a very substantial return. Mrs. Maryat had previously given to the Dundee Royal Infirmary £10,000 to clear off the deficit on accounts and £75,000 to provide an X-ray and medical electrical department.

A POST GRADUATE course in dermatology and syphilis with special reference to therapeutics will be held in Vienna from February 13th to 25th. Particulars may be obtained from the secretary of the international post-graduate courses, Dr A. Kronfeld, Porzellangasse 22, Vienna IX.

THE first international congress of mental hygiene will be held at Washington in April 1923.

WE have received the first issue, dated September 1st, of the *Revista de Neurologia y Psiquiatria*, a Medical Journal in Spanish, a monthly journal published at Montevideo under the auspices of Dr. Americo Piccolini, M.D., professor of clinical neurology and other members of the Montevideo medical faculty. The journal aims at original articles on the pathology and treatment of nervous and mental diseases, and the current literature, society, intelligence and medical news.

THE November-December issue of *Norsk Tidsskrift for Læger* contains the obituary of the Norwegian Medical Society is dedicated to Dr. F. G. Gale, who has recently retired from the editorship of the journal.

SIR D. ARCY POWELL, B.E., one of the representatives of the Ministry of Health in the Metropolitan Asylums Board since 1921, has resigned on account of ill health.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863**, and **9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are

**EDITOR OF THE BRITISH MEDICAL JOURNAL, Antiology Westcent, London**

**FINANCIAL SECRETARY AND BUSINESS MANAGER**  
(Advertisements, etc.), **Articulate Westcent, London**

**MEDICAL SECRETARY, Modiscera Westcent London**

The address of the Irish Office of the British Medical Association is **16, South Frederick Street, Dublin** (telegrams **Bacillus, Dublin**, telephone **4737 Dublin**), and of the Scottish Office, **6, Drumshough Terrace, Edinburgh** (telegrams **Association, Edinburgh**, telephone **24361 Edinburgh**).

### QUERIES AND ANSWERS

#### FREQUENCY OF MICTURITION

**DR J McWHIRLER** (Auckland, New Zealand) asks for advice in the treatment of a intermittent frequency of micturition in a man, aged 48, who is otherwise healthy and able to do an active day's work. The condition commenced about three years ago, without any obvious cause. The attacks of frequency last for several hours or days during which time the patient may pass urine as often as every hour. The attacks and remissions commence quite suddenly and without any warning signs. Radiological examination of the bladder and urinary tract on two occasions revealed no disease and the prostate gland is healthy. The urine is normal except for a trace of albumin and the presence of many coliform bacilli and a few Gram positive cocci, there is no evidence of vesical disease. Attempts were made to render the urine alkaline, but it only became neutral, and no benefit resulted. Two intravenous injections of a polyvalent *B. coli* vaccine produced transient rises of temperature, but had no other effect on the condition. Alcohol, particularly whisky, brings on an attack almost immediately, but diet seems to bear no relation to the frequency. A cystoscopic examination has not been made.

#### SANITIZATION OF SYRINGES AND NEEDLES

**MR T LOWLER WARD** (Ipswich) writes as follows in reply to an inquiry published on November 12th (p. 905) as to the best way of keeping syringes and needles, so that they can be ready for use without sterilizing by boiling.—The following solution is efficient. Dissolve 15 minims ether sulphur 2 diachmids, spirit to the ounce. The spirit should be basic industrial spirit, not methylated—(it is, without prejudice, it can be obtained from any wholesale druggist). I have used it for syringes, needles, etc., for the past ten years in the venereal and urogenital chancres, and no case of sepsis has supervened. It is equally useful for cleansing the skin before puncture or small operations, etc. The used syringe is washed under the tap, a small quantity of the solution drawn up into it, to get rid of moisture and then ejected, and the syringe replaced in the solution. If deposit occurs in the solution it can be filtered and used again. If my memory serves me right I saw the formula in the *Clinical Journal*, where it was stated that, as the result of experiment, a syringe that had been used for a virulent culture of *B. coli* was rendered sterile after immersion in the solution for three minutes. This solution is in general use at the East Suffolk and Ipswich Hospital.

#### CANCER AND DIABETES

**DR FREDERICK L. HOFFMAN** (consulting statistician to the Prudential Insurance Company of America, New York, New Jersey) writes in reply to "C. H. S." (*Journal*, October 29th, p. 810) who asked for information concerning the occurrence of carcinoma or other malignant disease in patients suffering from diabetes. In connection with the San Francisco Cancer Survey I obtained replies from a large number of living cancer patients asking among other questions as to whether the patient had suffered or was suffering from diabetes. Out of 834 male cancer patients 13, or 1.6 per cent, were having or had had diabetes, while the percentage for 602 female cancer patients was only 8 cases of diabetes or 1.3 per cent. The coincidence of cancer and diabetes is therefore relatively very small. The foregoing figures are confirmed by further investigations, which will be published in the near future. I allude to regarding the cases noted will be found in my fourth report on the San Francisco Cancer Survey.

#### INCOME TAX New Practice

"A F" sold his general practice three years ago and started a purely surgical practice. He asks if he is entitled to claim the present practice as a "new" one.  
\* \* Yes. The fact that the general practice was sold should have been sufficient to enable him to show that he was entitled as from the date of sale to exclude "general" practice receipts from his computation of liability.

### LETTERS, NOTES, ETC

#### BULLOUS ERUPTION AFTER PHENYLECHONOLIC ACID

"J. C. M." sends the following note of a bullous eruption following the taking of phenylechonollic acid. The patient, a middle-aged lady of 60, had been in the habit of taking a French proprietary preparation of the drug for attacks of general muscular stiffness and pain up to about twelve months ago. At this time, realizing that she was in for one of her usual attacks, she took three tablets, with potash water, in three doses during the day, in the evening she found that there were large bullae scattered over her face, neck, and the backs of her wrists and hands. A few months later a similar eruption followed the taking of two tablets. Owing to the distribution of the bullae being on areas supplied by C III to D I spinal nerves, I had an x-ray taken of her cervical vertebrae, and this shows some osteoarthritis of these vertebrae. About a week ago she asked me if she could take some more of the drug as she was in considerable pain and, in view of the fact that I said that I thought it was just chance that she had the eruption, I allowed her to do so. However, the bullae appeared after the taking of a single tablet. The question now is, "Do the bullae in any way depend on the ingestion of phenylechonollic acid?" I am not satisfied that they are so dependent, and the drug causes the general pain. But I feel doubtful in advising her to take it if the bullae are always to occur and it will be difficult to convince her of this. The bullae are not those of *D. herpetiformis*. They are very large and some of them on the neck will measure as much as 1 in. by 1 in. or 2 in. But they are usually preceded by a prickling and burning of the skin and to be involved I should like to know if any of you have seen a case of phenylechonollic acid.

#### LONG UMBILICAL CORD COILED ROUND NECK

**DR J. W. LING** (Anjou, British Columbia) writes. The case of multiple coils about the foetal neck reported on August 27th (page 349) recalls to mind a similar case. A multipara, aged 31 in her third pregnancy, gave birth to a full-term male child weighing 6 pounds in the North Vancouver Hospital. Six coils of the cord were removed from the neck of the child when the head was delivered. Labour was normal, and was not delayed by the mass of cord about the neck. The child was healthy but the cord was very long about 50 inches, and was somewhat smaller than the average. Dr Ling adds. It would be interesting to know whether the coils occur because of the great length of the cord, or whether an added length of cord is developed to compensate for that portion taken up by the coils.

#### A WARNING

Information has reached the British Medical Association to the effect that there has lately called upon members of the Association in the Newmarket and Edinburgh districts a man calling himself as a graduate of Edinburgh University, 1918 and using the surname of a respected member of the Association who graduated that year. He said that he had been sent by the Royal Medical Benevolent Fund to Switzerland suffering from tuberculosis, and asked for money. Inquiries made of the Royal Medical Benevolent Fund elicited information to the effect that the Fund has sent no one to Switzerland in the circumstances mentioned. Any reader who may be the recipient of such a visit would be well advised to get into touch at once with the police.

The Automobile Association road patrols will not be on duty in England, Wales, and Ireland on Christmas Day. During the rest of the holiday season the A.A. road organization will work as usual.

*Lohmeyer's Pharmacologia*, issued to the medical profession by Oppenheimer, Son, and Co. Ltd. combines a synopsis of recent literature on the nature and use of drugs with a listing of spaces for vaccination and midwifery engagements, and general information likely to be of use to the medical practitioner. The 1928 edition has been carefully revised, and is of convenient size for the pocket.

#### VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 29, 30, 31, and 34 of our advertisement columns, and advertisements as to partnerships, associations, and locum tenencies at pages 32 and 33. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 74.

## An Address

OF

## CLINICAL RESEARCH BY THE FAMILY DOCTOR

DELIVERED AT THE ANNUAL MEETING OF THE ABERDEEN  
BRANCH OF THE BRITISH MEDICAL ASSOCIATION,

BY

A. MAITLAND RAMSAY, M.D., LL.D.,

HONORARY DIRECTOR, JAMES JACKENZIE INSTITUTE OF CLINICAL  
RESEARCH, ST. ANDREWS

THE position in which the doctor is placed immediately after graduation is really the outcome of the progress of medicine from the earliest times down to the present day. It has taken centuries for the healing art to emancipate itself from superstition and the thrall of authority. The reformation began on the day in the second century that Celsus boldly stood insulently, erst while the old commonplaces of authority, tradition and general consent, and put his finger on the pulse with the intention of trying to predict from the variations in it the course of the disease from which a patient was suffering. Here was the dawn of a new era in medicine, and from that time onwards the physician became a clinical observer. He had, however, nothing to help in his work except his highly trained senses and a mind stored with the results of his past experience.

As the centuries passed advances were made from time to time by men who were pioneers in their own day and generation, but the great awakening came when Virchow, about the middle of the nineteenth century, attempted to systematize all previous knowledge by his doctrine of cellular pathology. His work was epoch-making and its fundamental importance was quickly recognized. Its keynote was the thorough study of the structure of the organs or the body, no science of pathology gradually developed, and its discoveries had a profound influence on the practice of medicine. Laboratories were built and laboratory technique became greatly improved, and the practical application of morbid anatomy to clinical medicine resulted in the discovery of physical signs by means of which the physician was enabled to discover evidence of organic disease in the living subject. Definite objective evidence now in great measure took the place of the study of symptom, and led to a classification of diseases based on post mortem appearances. Structure therefore was thought to be of more importance than function, and the end results or disease were minutely investigated while its causation and its early stages were relatively neglected. Intense microscopical examination of pathological specimens was the order of the day and led to the discovery of micro-organisms. The nature of those minute forms or life, and the part they play in the causation of disease, were now eagerly discussed, and research workers were attracted from the study of alterations in structure to the investigation of disorders of function.

Physiology now came to the forefront and was recognized as the only basis on which scientific medicine can rest. What may be called the descriptive stage of medical study was gradually superseded by an experimental stage. Laboratories and laboratory methods were again greatly extended, numerous instruments of precision were invented, and the techniques of the pathologist were no longer confined solely to the post mortem room. He took a share in the examination of the patient and called himself a clinical pathologist. In the early days of the study of disordered function the physician and the clinical pathologist were frequently combined in one person. That was a very satisfactory arrangement, but it did not last long because as method of examination became increasingly complicated the pathologist tended more and more to isolate himself in his laboratory and to lose touch with the clinician. He also began to bring to the solution of his problems the spirit and the methods of research in the exact sciences. His ambition was to make his observations definite and unambiguous, and so it came about that the clinician, oftentimes worried and disappointed by his failures at the

bedside, became tempted more and more to appeal to the laboratory worker to provide him with a test which would give a short cut to diagnosis. This passive attitude on the part of the clinician led to the assumption of a rather aggressive attitude by some laboratory workers who claimed that all research for the advancement of medicine ought to be left in their hands.

As a result of this unnatural distinction between practice and research the methods of the clinician through which so much had been achieved in the past tended to fall into the background. That was a retrograde step, because the true aim of all medical research is to reconcile the results of laboratory examination with the clinical symptoms. Much purely laboratory investigation has failed for want of clinical direction. It is true that phenomenal results have followed experimental research, but it must not be forgotten that some of the most notable achievements in medicine have been accomplished by men whose life was spent far removed from laboratories or seats of learning. Take four examples. Harvey was an obscure physician struggling to make a living when he first began to think of the circulation of the blood. Jenner and the worries and vexations of a country practice discovered vaccination. Koch was a district physician when he began his investigation on tuberculosis, and Mackenzie was a busy general practitioner when he laid the foundations of his epoch-making work on the heart. The best progress is likely to be made when clinician and laboratory worker pull together, each realizing the difficulties of the problem constantly encountered in general practice, and both determined that those difficulties shall be solved as a result of their mutual efforts. Some pathologists who have been trained wholly in laboratories are quite ignorant of the problems which confront the general practitioner in the course of his daily work. They are impatient of clinical observations, which they say are wanting in scientific precision, but they are only too easily led astray by the apparent exactitude of physical and chemical formulae.

When dealing with living tissues one cannot depend wholly upon rigid mechanical fidelity; formulas cannot be applied in the expectation that the result will be obtained with strict mathematical precision; there is not a rule and a measure in all things. Pain cannot be measured by any instrument or precision, yet it is one of the most valuable symptoms of disease. The true value of the laboratory in the study of clinical medicine is enhanced rather than lessened by a frank recognition of its limitations.

Although there is no reason to think that the principles by which medicine is governed are materially different from those governing other art and science, yet the method of the sciences allied and ancillary to medicine cannot be applied without certain reservations. The problems of disease are more complicated and difficult than any others with which the trained mind has to grapple. Each individual case presents its own problem and therein lies its special interest. Nature is constantly performing experiments in the laboratory of the human body, and although the reactions the result of those experiments are far too delicate to be measured by test tube or balance, yet they are revealed by the occurrence of symptoms.

The methods of research in clinical medicine are therefore peculiar to itself, and the kind of knowledge necessary to detect the earliest symptoms of disease can be best illustrated by the general practitioner because it is he alone who sees disease in its initial stage. It was not that I recall that the late Sir James Mackenzie founded the Institute for Clinical Research in St. Andrews. He insisted that it is only the general practitioner who has the opportunities for clinical research into the early stages of disease—that is, before the patient's disability is sufficient to take him to hospital. He, and he only, has the fascinating task of recognizing disorders while prevention is still possible.

Many of the great teachers of the past were to all intents and purposes general practitioners. Laboratory methods were unknown to them, and they possessed no instruments of precision, but they studied the clinical in their own powers of observation, and taught their students how to use their unaided senses. The neglect of this form of education renders the medical student of the present day less self-reliant in diagnosis and prognosis than many

of his predecessors. What has been gained, therefore, in one direction has been lost in another.

Mackenzie firmly believed that the family doctor could do as much to advance the science of medicine as any worker in a laboratory, and the goal of his ambition was to find ways and means to enable him to become a research worker. The idea of founding an institute for chemical research had long been present in his mind, and when the opportunity came he left London at the very zenith of his fame and settled in St. Andrews. He realized that his plans, as he conceived them at that moment, could only be carried out in a town of small size with a comparatively stationary population. In a letter which he wrote on the day before he died, he says:

"When I left London I dared not tell anyone the real reason of my leaving, for it would have been looked upon as a piece of folly. For years I had been gradually becoming convinced that the whole tendency of research was on wrong lines. It was devoid of fundamental principles, was haphazard, and could not supply the kind of knowledge which would enable us to solve medical problems. It was with the object of searching for this principle that I undertook, at the age of 65, the burden and responsibility, which were very heavy, of starting an institute for the purpose of this quest."

So it came about that the James Mackenzie Institute was founded in St. Andrews. For five years it enjoyed the immeasurable advantage of Mackenzie's presence and direction, and his great and forceful personality dominated its work. The general practitioners of the district gathered round him, and week after week they sat down together to discuss problems of far-reaching influence on the progress of medicine. He spoke to those family doctors like an elder brother, and all felt that to be associated with him was both an education and a revelation. His teaching has opened a great and unforeseen road in clinical medicine. He ever insisted on the habit of accurate observation, and while not fond of controversy for its own sake, or even contradictory, he was ready at all times not only to defend vigorously the existence of his own work, but combative and eager to fight in defence of his own opinions. His writings are all based upon his own carefully recorded observations. He always insisted that departure from health is made manifest at its onset by sensations experienced by the patient, and that failure to detect disease in its earliest stages is due to the fact that the patient's sensations are not systematically investigated.

With rare sagacity Mackenzie formulated certain principles underlying the production of symptoms, contending that in medicine, as in physical and chemical science, although the phenomena of disordered action are many and varied, the causes underlying their production are few. He founded his institute to develop those principles, to put them in practice, to test their accuracy, and modify them in the light of experience. He was never satisfied unless he was testing constantly and improving in detail. He had no sympathy with those who never change their mind, and, far from apologizing for inconsistency, he would denounce consistency as an evidence of mental sterility and an attribute of those who have no mind to change. Nevertheless, although he might be ready to admit that he was wrong on Monday he would be equally positive that he was right on Tuesday, and if called upon to argue in favour of his opinions he always spoke with intense conviction.

There are many who believe that the secret of progress in medicine is to be found only in the laboratory, and choose that walk in life rather than engage in general practice because they consider that it is the only way to study medicine scientifically. The scientific spirit, however, is not the exclusive property of the laboratory worker. It is unborn in the individual and whoever is possessed of the true scientific spirit can bring it to bear in the solution of any problems with which he is confronted in the course of his daily work. The observant physician possessed of the critical faculty can do more to advance medicine by his work at the bedside than many who lead a sheltered life in a laboratory. The investigator who aims at extending the boundaries of knowledge must have initiative and courage, and above all must possess vision, for without that uncanny power of seeing into the nature of things and discovering secrets hidden from others the laboratory

work may obscure the path of progress and become a real danger to the advance of knowledge.

The chief purpose of a laboratory training is not to teach the students how to use laboratory instruments or to perform complicated chemical tests. The invaluable gift of the laboratory is its discipline in scientific method, and its training in the importance of logical reasoning and the use of exact language in speaking and in writing. The scientist is always distinguished from the empiricist by his accuracy in measurement, by his precision in statement, by his honesty in accepting and handling evidence, and by his fairness in presenting it when contesting the opinions of those in opposition to his own views. In that sense every general practitioner should be a research student, and the family doctor ought to train himself to employ scientific method at the bedside in the same masterly manner that it is used by the worker in the laboratory.

Chemical medicine in the past has been so much a matter of personal skill and experience that when the clinician dies his work dies with him, whereas the results of investigations in a laboratory are recorded so carefully that something tangible always remains to enable one worker to take up a subject at the stage where another has finished. There can be no doubt that skill in diagnosis, and more especially skill in prognosis, must always be largely a matter of individual experience, but it, such valuable knowledge, gained during a studious life, is not to be lost when he who accumulated it dies, some means must be found to provide a foundation on which future investigators may build. That is one of the chief aims of the Clinical Institute, where accurate observations of the disturbance of the processes regulating the function of the different organs of the body are carefully recorded. The crisis is reviewed at regular intervals, when all the symptoms are reconsidered, and an attempt is made to distinguish those due to disturbances of those processes which are essential to the maintenance of life from symptoms due to the interference with processes which are not essential to life. The "follow up" is of the first importance in all records, because without it the case is of no clinical value, what is wanted is the patient's medical life-history, consequently the disease must be under observation from its onset to its termination.

It is generally supposed that the greater the number of patients a doctor sees the greater his experience and his knowledge. That is only a half-truth, because a doctor may see hundreds of patients, and be most meticulous in recording the symptoms during a passing phase of the disease, and yet be none the wiser regarding the prognostic significance of any one of them. Mackenzie always insisted that "prognosis is the motive which inspires note-taking with the birth of life, making the notes a personal source of knowledge that can be applied in the practice of medicine."

What is needed most of all is that the research student in the laboratory should get into closer touch with the realities of clinical medicine, because any cleavage between the laboratory worker and the general practitioner impoverishes both. There is no life in the ordinary text book on laboratory methods. The doctor in the country finds little use for tests he cannot readily apply at the bedside of his patient. The clinician can never be replaced by the laboratory worker. Each is complementary to the other, each has much to give and much to gain. I can well believe that the laboratory worker does not realize how much the clinician has lost in recent years by his reliance on the laboratory for help to diagnose disease, when by a careful study of symptoms he might have recognized it for himself. We must look to the living, to him, the laws of life, not to the dead. The true clinician never gets into a rut. He at all times feels the urge of adventure and discovery. He must always have an open mind, and when, in the course of research, facts are discovered which are opposed to accepted theories, the hypotheses must be abandoned even although supported on high authority. Work of that kind requires much persevering effort and much patient waiting for proof, but the goal aimed at must always be indisputable accuracy. Evidence can be accepted without the most rigid criticism.

The clinician must try none and more to than in the

of the normal rather than of the abnormal. It cannot be repeated too often that the symptoms of disease are only the phenomena of occurrence of the status of exhaustion due to over-exertion of the organ when in its state of health. It will be a great gain when the experimental physiologist gets into the habit of leaving his laboratory from time to time in order to visit the wards, the dispensary and the operating theatre under the guidance of the physician and the surgeon.

A new clinical physiology is much to be desired—a physiology which deals with the symptoms of ill health and tries honestly to estimate the functional activity of every organ of the body. The more the apparently simple matters are investigated the greater will be the respect and astonishment to find so many gaps in our own knowledge. Mieschke never tired of trying to drive that fact home. He took a delight in astonishing his visitors by such questions as the following: Why does cancer kill a man? What is it that kills him? Why does he die? At those times his conversation was fascinating and stimulating but sometimes very puzzling and bewildering. It was necessary to admit that usually the questions he asked although going to the very root of the matter and proving how ignorant we are of some of the most fundamental problems of life are in the present state of our knowledge unanswerable. Doubtless by the advance of science and the increase of knowledge those problems will one day be solved and I venture to predict that the family doctor will play an important part in their solution.

## VILLAGE SETTLEMENTS FOR THE CONSUMPTIVE

ABSTRACT OF THE MITCHELL LECTURE FOR 1927 \*

BY

P. C. VARRIER-JONES, M.A., MRCS L.R.C.P.,  
MEDICAL DIRECTOR, FAWCOTT VILLAGE SETTLEMENT

PERHAPS in no disease more than in tuberculosis has the outlook changed so much in recent years. With the progress of modern research its horizon has widened its problems have multiplied, and the work to be done increased. Indeed, the medical profession is marching on the whole, abreast of the time, for it is now recognized that in that common disease tuberculosis a number of conditions must be studied and provided for—a complex involving medicine, sociology, psychology, and economics.

A diseased organ is now considered in relation to its environment. Formerly it was only the affected organ apart from the rest of the body that attracted attention but gradually the conception of the interaction of organ and organism and the interplay of forces 'resistance' and immunity were taken into account. It is now essential to go a step further by recognizing that environment plays an important part not only in the propagation of but also in the fight against, disease. The recognition of this factor of environment makes it possible to combine the purely medical measures directed towards cure with the medico-social effort designed to prevent disease. As soon as the social aspect of cure and prevention is established educational health work takes its rightful place in the State.

Now it is obvious that if these ideas are to be carried into effect the opportunity must be provided for putting them into practice. An environment must be provided in which the following considerations have due weight: the functional power of the diseased organ within the organism must be protected so as to avoid exhaustion and indeed further impairment and the patient as a whole must be so situated as to avoid opportunities which may impair his power of resistance and recuperation. These ideas represent a great advance on that of the mere passive or active treatment of disease by ordinary therapeutic measures. Their acceptance presupposes a field of vision extending far beyond hospital or laboratory walls. It postulates a study of social and economic laws too often neglected by

the medical profession. It opens up a new field for research and an ever widening scope of industrial conditions of employment—and not of the healthy only, but of those who, on account of their disability, cannot keep pace with the able-bodied, and who, even if they could keep pace, are potential 'carriers' of disease.

Gradually the State attempted—and not without success—to grapple with the disease, both from the individual and from the community point of view. Sanatoriums were erected all over the country, some managed by private philanthropic agencies, others by local authorities, counties or county boroughs. It was soon obvious that the poor required further care after the period of early treatment had been completed. Statistics show that from 27 to 64 per cent of patients die within five years after leaving the sanatorium, a great majority of them dying within the first two years.

It is intelligible why patients do not enter a sanatorium until the disease is well established. The early symptoms of pulmonary tuberculosis are so vague that it is quite natural that the patient's attention should not be seriously challenged by them. Thus it is that the consulting physician and even the family doctor, too often never see the patient until the disease has done much of its insidious work. The reasons for the failure of early diagnosis and still more of early treatment lie in "human nature" and in economics. Is it not because in the case of the well-to-do the human factor, and in the case of the working man the economic factor has been ignored that a system for the treatment of patients has been built up at a stage when they do not and so far as can be seen at present will not come up for treatment? For such cases our large sanatoriums are waiting and wait in vain.

It has been said that 25 to 55 per cent of the cases of pulmonary tuberculosis remain unnoticed to the local authority and that the cases that are notified come for the most part from those on the lower rungs of the social ladder. On the higher rungs the notifications gradually become fewer and finally near the top cease altogether. Are we to assume that in the higher social scales tuberculosis is rare or unknown? Observation convinces me that this is not so, the condition is recognized but it is too vexatious to be faced boldly and promptly. It is therefore not surprising that sanatorium treatment in the majority of cases does little more than patch up the damaged organ; it is far from assuring complete arrest of the disease. One of two courses must eventually be adopted: either sanatoriums must adapt themselves for the treatment of cases without any prospect of complete arrest of the disease or a new system must be inaugurated which will do so further in addition to whichever of the two policies is adopted, preventive measures must be taken to stop the spread of infection.

It must however reluctantly be admitted that in 75 per cent of the patients now sent for treatment to our sanatoriums complete cure is out of the question. Efforts to obtain the case early will quite rightly continue to be made but how to deal with those in whom the disease can at best be only arrested is a most difficult problem for in more than 50 per cent of the cases now seen in sanatoriums arrest is far from permanent.

The most difficult problem and the most frequent patient is the man or woman in whom the disease has had its way for some considerable time and in whom permanent damage has been done. Were the main problem of tuberculosis as is constantly stated the treatment of the early case and this only, why are there still so many schemes for air cure, farm colonies and the like? The sanatorium, with its adjunct the dispensary, should meet all requirements. But this condition is now known to be a figment of the imagination, the reality is much more serious. It is not as it is upon attention and usually emphasizes the failure of sanatorium and dispensary. The position must be reconsidered. The popular opinion based upon certain findings of pathologists in laboratory work that tuberculosis is a fully curable disease does not stand the test of clinical results.

How different is the picture of the treatment of early tuberculosis from that observed day in and day out in a tuberculosis dispensary, where seriously damaged patients

\* Delivered before the Royal College of Physicians.

and crowded together, waiting for the cure which never comes, supported by small doles of food and medicine which prolong a pathetic and fruitless existence, with nothing but failure and disappointment at the end of it. Little or no effort is made to provide conditions permanently suitable for the patient's relief, and for the most part he is left to drift, or is beguiled by ignorant advisers to embark on reckless adventures. Must it not be confessed that the system of tuberculosis dispensaries and sanatoriums is now carried on, is founded upon a wrong reckoning?

Various schemes have been inaugurated to consolidate the position of those who, after a period of sanatorium treatment, have reverted well. These have been described as hardening-off processes, and both in this country and America have been followed with keen interest. The colony was started almost entirely with the object of prolonging sanatorium treatment on more economical lines. It was soon observed that certain patients, with a localized and early lesion which had become wholly or in part healed by a term of sanatorium treatment, and patients whose general resistance to the disease was great, benefited to no small extent by light employment in the open air, but when patients, even when most carefully selected, were advised to follow a similar occupation after leaving the colony the result was seldom successful.

In training tuberculous men for reinstatement in industry we are attempting what is well-nigh impossible. The organism is damaged, and damaged for ever, and the ordinary industrial environment is unsuited for its life. Add to this the incubus of providing for a family, and the position quickly becomes impossible. Tuberculosis is a fluctuating disease, and as such needs continuous medical care. It needs a thorough understanding of the principles underlying both health and industry, all of which can only be carried out under a special scheme.

The principles underlying Pipworth and the Altio workshops of New York<sup>2</sup> (where now arrangements are being made for the permanent residence of the workers in flats adjoining the factory) differ fundamentally from those of the Reco workshops of New York,<sup>4</sup> where training of the substandard man was the only objective. Recognizing that the necessary conditions are unattainable in the outside world, no effort has been made at Pipworth to train men for an occupation outside the settlement. On the contrary, all endeavours have been directed to providing permanent occupation for such men in the settlement at a full rate of pay.

In the village settlement, first and foremost, there must be the guarantee of a living wage. To provide suitable housing accommodation without providing the means to pay the rent goes but a very little way. To pay the man's rent destroys his self-respect, and, unless care is taken, the result will be a pauperized individual. Some men, therefore, of maintaining his earning capacity must be devised so that he may be able to pay his rent.

To enable the consumptive working man to maintain his earning capacity a whole set of conditions must be provided. Work, in the first place, must be such that his strength shall be equal to it—that is, it must be congenial, it may be the work of a craftsman (if the man's mental processes are equal to it) or it may be repetition work (if the man is of such a nature that he will not readily accept responsibility). But in either case it must not be playing at a trade. If there is one thing which a working man is able to detect quicker than another it is the sham industry or sham trade which has been set up by the institution for his benefit. If his employer is playing at the game, so will he.

The most important consideration is the avoidance of all exploitation of his labour. It seems self-evident that a scheme for the employment and benefit of the tuberculous man should be for his benefit, and his only. This is by no means always understood or acted upon. There is no need to invoke a kind of feudal system in which all the best positions are taken by healthy overseers and the disabled left in the position of serfs. The true village settlement for the tuberculous will be one in which there is an opportunity for all to attain to a better position, just as it is possible in a modern well managed business concern.

A village settlement should be regarded as a self-contained community, its inhabitants being substandard men and women. They can compete with one another and no stimulation by such competition, but they must not be in the bondage of the healthy—those inhabitants of a foreign country, the outside world.

What the disabled man requires is the opportunity to put his talents to good use, the provision of that opportunity is our business. The provision of opportunity is quite a different thing from charity, charity paralyzes effort. The provision of opportunity is rather the protection of the disabled from fierce and unequal competition than anything else. To introduce such competition into the village settlement in the form of a healthy overseer is to court disaster. This is hardly ever realized. The healthy overseer demands good pay, but he rarely earns it. Unless he is a man of exceptional character he looks upon the reduced working capacity of his men as a reason for reducing his own, he will come down to their standard rather than attempt to lift them up to his—which is a rule as dangerous as impossible. His salary becomes a drag on the industries. The overhead charges increase, and it is just these which the disabled man cannot meet out of his industry. He can earn his own wage, but little more. Hence lies the secret of the non-employment of any large number of disabled men in ordinary industry. A sympathetic employer can afford one or even two, but the point is quickly reached at which the subsidy required to keep these men equals the profits of the firm. A penny an hour lost on each of 300 men working eight hours a day reaches the astonishing figure of £2,800 a year. A donation of £50 or £100 a year to charity is an easy way of reaching such a disaster.

The village settlement is the ideal scheme for the after care of the tuberculous worker, whether man or woman. Sir George Newman, in his various reports,<sup>5</sup> emphasises the point. There is a certain amount of agreement as to the ideal, and it remains therefore largely a matter of detail and of application.

It will be seen that the village settlement is gradually evolved from the sanatorium. To start a settlement *de novo* would not be attended with success. A village settlement grows as naturally as any village would grow when an industry which offers employment springs up. The difference between a village settlement and the ordinary village is that the industries are specially run for the benefit of the inhabitants of the village settlement, and no one else. The spirit of co-operation, once implanted grows and increases, self-help and self-guidance follow. The institutional spirit is transformed into that of self-reliance without which no community can stand.

The village settlement, with its hospital for advanced cases, the sanatorium for those suitable for this form of treatment, and the village, with its hostels and hotels, workshops and recreation halls, forms a complete unit. The opportunity for medical research must not be lost sight of, and this aspect, combined with the opportunity for investigation into industrial and social conditions, makes the whole scheme an entirely new departure.

#### The Results

1 A complete absence, during eleven years, of clinical tuberculosis in the 133 children of men and women who are definite clinical cases of the disease and in most of whom show tubercle bacilli in sputum from time to time.

2 A village community maintained by the work of the industries.

3 A total of £72,000 paid in wages to the settlement since 1918.

4 An aggregate of sales of goods produced by the settlement amounting to £177,543 during that time.

5 The arrest of the disease, prior to such an extent as to justify an expectation of life three times as long as is usually given in sanatorium statistics.

6 The removal of a number of chronic tuberculous cases from the homes and workshops of the general community.

The question was once asked: What effective control can such permanent village settlements be said to exercise?

The entire body (back and front) has been exposed to irradiations from a mercury vapour lamp (or preferably to the rays of three of these lamps used simultaneously) twice weekly for a period of six to seven weeks, the minimum exposure being ten minutes to both back and front of the body, at a distance of about 16 inches from the burner. This is followed by a rest for one month, and then the patient undergoes a second (and, if necessary, a third) course. I have aimed at producing a second or even a third degree erythema at each exposure, in other words, the irradiations have been intensive rather than mild.

The majority of these cases were sent for treatment by their own doctors after other methods had yielded indifferent or negligible results, and in only 5 of them (12.5 per cent) was there no appreciable improvement. In the remaining 35 cases (87½ per cent) marked improvement resulted, as evidenced by increased co-ordination and steadiness of muscular control (both in grosser movements, such as walking, and in the finer movements of dressing, feeding, etc.), cessation or diminution of excessive salivation, disappearance of pain and insomnia, increased sense of mental vigour and physical well-being, and relaxation of the mask-like facial expression. In 2 cases out of the 5 apparent failures extended trials were given, the other 3 failed, for one reason or another, to continue treatment after the first three weeks.

The patients whose cases are recorded below are typical of the series treated.

**Case 1**—An artisan, aged 22, had contracted the disease eighteen months before coming for treatment. This was a well marked case of post-encephalitic Parkinsonism, with marked hypertonus, tremors, sialorrhoea, and pain in his throat. After a first course of irradiations he showed great improvement, feeling much better in his general condition, and using his hands easily. Thus he was able to feed and dress himself, but his throat was still troublesome. After a second course of irradiations the general improvement could only be described as excellent, he was walking and talking well, his legs were much stronger, and his upper limbs were practically free from tremors.

**Case 2**—A married woman, aged 47, had suffered from the disease for nearly two years. She was unable to feed or dress herself, and suffered from nerve pain and marked depression. Now after ten exposures (five weeks), she is much brighter and stronger, is feeding herself, talking, eating, and walking well.

**Case 3**—An artisan, aged 25. Parkinsonian syndrome well marked. Improved considerably from the very outset. Walked better after five exposures and felt considerably stronger. After a second course he is now eating, sleeping, and talking well. Feels his legs and body generally to be much stronger, has regained almost complete confidence in himself, has completely lost the characteristic facial expression, and is now back at his job, and working well.

**Case 4**—A married woman, aged 32, had contracted the disease two and a half years before coming to the clinic. Her tremors, inco-ordination, dragging of the legs, excessive salivation, and helplessness were silent features in a characteristic condition. After fourteen exposures she was able to dress feed and help herself. She felt a peculiar degree of mental stimulation and a definite sense of increased steadiness and strength for twenty-four hours after each radiation. She is now greatly improved.

**Case 5**—A man, aged 44. Onset of disease four years ago. During the last two years he was getting definitely worse. Twelve irradiations have so far been administered, and the patient is to day brighter, happier, and stronger, his expression has softened, and his tremors have become subdued. He expresses himself as feeling "much stronger, and better altogether."

**Case 6**—A man, aged 51, had typical Parkinsonian symptoms with distressing salivation, and paresis of right arm. Has improved from the first exposure, salivation is diminished and he is now using the right arm and fingers with comparative ease.

**Case 7**—A woman, aged 18, was treated for an acute attack of encephalitis lethargica in the General Hospital four years ago. She has so far only had eight exposures, but already shows increased strength, vast improvement in talking, and good general improvement.

**Case 8**—A clerk, aged 28. This patient had treatment spread over several months. He can now dress, undress, and feed himself, his general improvement being remarkable. He is brighter, stronger and more steady in every way.

**Case 9**—A woman, aged 19. Two years' history of illness. Was much improved, stronger, and free from excessive salivation after a course of seventeen irradiations. On cessation of the first course of treatment she became worse (possibly because she had had too many consecutive exposures), but after a lapse of one month she had a further twelve exposures, and showed marked improvement.

**Case 10**—An artisan, aged 30, had contracted the disease three years before coming to see me. Tremors, salivation, and paresis have improved greatly after eight exposures in his second course.

## DISSEMINATED SCLEROSIS THE RAT AS A POSSIBLE CARRIER OF INFECTION

BY

ISABEL G. H. WILSON, M.D., D.P.M.,  
PATHOLOGIST TO TWISTOCK SQUARE CLINIC 107, FUNCTIONAL NERVOUS  
DISORDERS, CLINICAL ASSISTANT PRINCE OF WALES'S GENERAL  
HOSPITAL, TOTTENHAM

THE purpose of this article is, first, to set forth some statistics on the occupational distribution, and death rate of disseminated sclerosis, and secondly, to discuss these, with the occupational history or a series of clinical cases, in their bearing on the theory that the virus of the disease may be spread by the rat.

### OCCUPATIONAL INCIDENCE

Through the kindness of the Registrar General I was able in 1926 to investigate the occupations of 688 persons who had died of disseminated sclerosis in 1925. The occupations were classified as far as possible, and then the actual number of deaths in a given occupation was compared with the expected deaths. By "expected deaths" I mean the number of deaths which would have occurred from disseminated sclerosis in those following a given occupation if the deaths had been evenly distributed among the population. For instance, if one-twentieth of the population are clerks, one-twentieth of the 345 male deaths from disseminated sclerosis should be among clerks. The matter is not so simple as it looks, but the advice of the expert staff of the Registrar-General on dealing with the figures has, I think, eliminated such error as is avoidable. The figures are as follows:

	Expected Deaths	Actual Deaths
Miners	19.17	20
Clerks	11.95	11
Farmers	7.46	16
Farm labourers	12.98	15
Railway workers	8.63	11
Carpenters	5.53	9
Painters and decorators	4.36	7
Gardeners	5.33	8
Plumbers	1.21	3
Moulders	1.91	3
Grinders	0.43	2
Window cleaners	0.39	2

The summary of the full statistics is as follows:

	33	Relatives	23
Farmers and farm labourers	33	Relatives	23
Gardeners	8	"	8
Labourers	37	"	16
Workers in chemists and dyes	6	"	2
Domestic and nursing	27	Relatives	12
Cotton workers	25	"	1
Wool workers	13	"	10
Boot and shoe makers	7	"	8
Carters, etc.	12	"	7
Timber workers	17	"	12
Painters	8	"	5
Building trades	8	"	3
Printers	9	"	
Clerks and teachers	30		
Army pensioners	11		
Engineering and plumbing	19	Relatives	13
Railway workers	11	"	11
Ships and fishing	8	"	9
Iron and steel	22	"	14
Mining industry	26	"	11
Foodstuffs	22	"	25

The remainder may be classified as "Miscellaneous."

### GEOGRAPHICAL

The death rates were calculated for 1925 in the different counties of England and Wales. A greater range of years would have been much more valuable, but the labour involved was greater than I could then undertake. The death rate for the country as a whole was 17.5. This does not mean that the 1925 rate was lower than the death rate at all ages of 18.2 for the period 1921-25, but merely that the 1921-25 figures include diagnoses on certificates which were only presumed to be those of disseminated sclerosis—for example, "spinal sclerosis." Such doubtful diagnoses were eliminated from the 1925 figures considered separately, and consequently the number of deaths is apparently smaller.

\* Part of this is accepted for degree of M.D. by Edinburgh University. October 1926. A grant was given by the British Medical Association towards the cost of this work.

The highest death rate for 1925 was in the State of Pennsylvania—103.3, then follow Merioneth 91, and Monmouth 83. Middlesex, Dorset, and Buckinghamshire were lowest, all having death rates of less than 9 per million.

There is reproduced by permission the map published in 1921 by the American Association for Research in Nervous and Mental Diseases, which shows the prevalence (not death rate) in America. It will be seen that the heaviest incidence is round the Great Lakes beside the slow-flowing navigable portion of the Mississippi, and in one or two other areas.

#### DEATH RATES FOR DIFFERENT AGES

Again by courtesy of the Registrar General I was given the figures showing the death rates at different ages for the years 1921-25. Graphs of these show an interesting difference between the curve for males and that for females. It is of special interest to note that the death rate is much more like that of all illnesses taken together than would be expected from a disease thought to attack young persons and believed to have an average duration of about eight years. Probably the explanation is that the illness last much longer than was formerly supposed. In the series of 72 cases recorded below two patients had suffered from disseminated sclerosis for over twenty years.

#### THE RAT AS POSSIBLE CARRIER

This possibility is put forward tentatively. The following facts gave rise to it. The late Dr J. W. Dixon, to whose work so many owe in part, reported the case

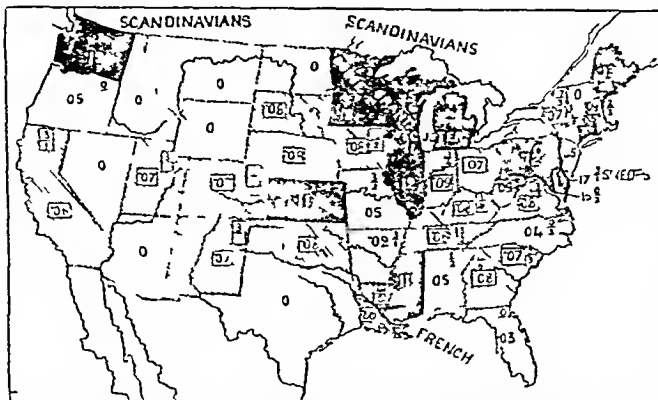

Spirochaetosis icterohaemorrhagica is caused by a rat- and water-borne leptospira, which has probably two phases (as has also the spirochaete of syphilis and that of relapsing fever), the infective phase developing in stagnant water. The spirochaete of disseminated sclerosis—which is mentioned in the descriptions of some sixteen sets of avowedly

successful experiments to find or to transmit this organism—is described as resembling closely the leptospira of Weil's disease. Here are two pieces of circumstantial evidence.

The clinical similarity between disseminated sclerosis and chronic spirochaetal infection has often been commented upon and recently by Adams. Adding to the spirochaete theory it might be suggested that variations in the life cycle of the spirochaete are responsible for the small to the large incidence in the population (only one phase being infective) and for the failure of

many investigators to find the organism (one stage being non-spirochaetal), that this organism is carried by rats, is excreted by them into water and where the water is stagnant develops its infective phase that the organism gains entrance to the patients by penetrating the mucous membranes of those who fall unexpectedly into infected water or more commonly through the skin of the hands, arms or feet or those who develop the disease as the result of occupational exposure and that this entrance through the skin is facilitated by continuous dampness of the skin and probably also by abrasions and dermatitis, occupational or other.

Going back to the former statistics the incidence is

Map of the United States showing the prevalence of disseminated sclerosis by state. The numbers in the Great Lakes region are the names of the carriers which the disease has been found to be carried by. From a table found in 'Drafted Me' (1917) by J. W. Dixon. Reproduced by permission of the American Association for Research in Nervous and Mental Diseases (1921). The original map is a table which has been omitted here for the sake of brevity in reproduction.

Age	Male Population.			Female Population.		
	No.	Death	Rate per Million	No.	Death	Rate per Million
0-5	17,222,3	4	0.2	17,045,0	6	0.4
5-10	15,600,112	4	3.2	17,524,412	61	3.5
10-15	13,230,433	119	9.0	14,332,903	137	11.7
15-20	12,557,618	24	20.4	14,339,647	221	2.3
20-25	10,900,048	63	33.1	11,905,901	47	3.5
25-30	7,233,730	99	68.4	8,055,377	111	51.0
30-35	3,823,120	30	50.9	4,755,577	261	50.1
35-40	1,166,193	53	8.0	1,744,600	107	57.0
40-45	1,934	5	1.5	2,610,23	11	41.7
Total	91,800,63	1,702	18.5	1,039,603	1,737	17.9

Disseminated sclerosis—death rate per million at different ages (1921-25). In the chart continuous line = males; dotted line = females.

of a patient who developed disseminated sclerosis after falling into the deep end of fresh water baths. Charcot also mentions a case arising after the patient had fallen into water and allowed his clothes to dry on him. 'Mau on Bui' wrote of a man who suffered from prochlorosis icterohaemorrhagica after falling into the Thames. In something coming to my notice one after the other suggested a possible etiological resemblance between the two diseases.

heavy among farmers and farm labourers, and Adams has pointed out among those who work in byre and with cows. These statistical investigations of 1920 and the clinical experience of Adams coincide. With regard to the former I have remarked that 'the damp or cold sheds and byres and barns from the presence of rats and the neighbourhood of the farm water supply is perhaps more likely to be infected than the ground of the open fields. Gardeners

have obvious sources of infection if the theory holds good, so also live plumbers, with their hands in water, moulders working with wet sand, often rat-infested, grinders who hold their tools under a drip of water from a can, window cleaners obviously, and printers from the washing of rolls and roughening of hands from sandpapering, which is the occupation of the young decorator or the man working with a small firm. Cloaks have only very slightly less than the "expected" number of deaths—perhaps because the semi-invalid takes to cloaking, as he becomes unfit for harder work. Cotton and wool workers seem to have a heavy incidence (often they work with materials kept damp from a tank), but could not be further dealt with owing to difficulties of census classification. I am unable to explain the aged heavy incidence on wood workers, on the basis of the present theory.

Geographically, I should like to suggest that the rice inhabiting the Great Lakes area of America which is of importance in the etiology of disseminated sclerosis is not the human *Scandinavian*, as was suggested by the Americans, but the rodents *Rattus rattus* and *Rattus norvegicus*. If the spirochaete infests water, it is interesting to see that the Great Salt Lake is too strong for it. In England the fen district of Peterborough is infected, if any value can be attached to the figures of one year.

### CLINICAL

A series of 72 cases of disseminated sclerosis has been investigated with regard to the exposure of the patients to damp and wet in rat-infested areas. The classification made was as follows: "Positive," where there was definite history of working with hands or feet in water where the premises were known to be the resort of rats, or of sleeping in wet, rat-infested places, such were some bottle washers, and all the ex-service patients. "Probable," where there was continual dampening of hands or feet, as in washwomen and window cleaners, without evidence as to contamination of water by rats, or where the patient lived in damp, rat-infested quarters without special exposure to the wet. "Negative," where there were rats but no damp, damp, without special exposure thereto, and without rats, when the hands were in strong chemicals or disinfectants, and where neither rats, damp surroundings, nor wet occupation could be traced.

The history of damp and rats was considered over the four years preceding the onset of recognized symptoms—for the onset may be so insidious—and the same criterion was applied to the control series. Of these 72 patients 38 gave a definitely positive history, 14 probable, and 20 negative. Compared with these a series of 72 patients of similar age grouping, in hospital for diseases other than disseminated sclerosis, showed 21 positive, 7 probable, and 44 negative.

Of the 41 male patients, 27 had been exposed to all suggested etiological factors, 12 of them during their war service and 15 in other circumstances. The histories of some of these war-service patients are interesting. One man had been employed in water-pumping operations during the greater part of his service. He was constantly standing in water. Of the rest of the male patients 7 were classified under probable and 7 as negative. The 41 "controls" showed 17 positive, 5 probable, and 19 negative.

There were 31 female patients, of whom 11 gave a definitely positive history, 7 probable, and 13 negative. The histories for the control series were 4 positive, 2 probable, and 25 negative. It is to be noted, however, that these recorded as "negative" in both series were engaged for the most part in domestic work, and were only negative in the sense that special exposure to the suggested factors was not proven. It is, I think, to be expected that the female patient would have less definite knowledge of the rat factor. She works with water which may easily be infected with spirochaetes unknown to her (see report at St. Alexander Hospital on London waters). The man on the other hand, works in a bare or washes bottles or prints in a tank, and knows of the rats that run in the factory at night.

The histories of one or two of these patients may be quoted.

Mary worked in a vegetable kitchen, and constantly had wet feet from water on the defective flooring, where rats were seen at night.

Ann was a tin tester, and spent her days plunging tins into a tank to see if they leaked, with her arms in the tank. There were rats in the factory.

George and Phoebe had both been bottle washers in the cellars of a wine factory (where there were rats) when they developed their first symptoms, though he was a bottle's assistant and she a cork brander when they came under observation.

Arthur, a most intelligent patient, had worked on the wet and moulding beds of a Government works, and told how the mud would even go down his neck if he stooped near some too vigorous digger, and how dead rats were sometimes found in the mud.

John had only one grumble about his shoes in a campaign on a dry frontier—that he fought in a river bed, and, coming now and then on water, would walk through and allow his socks and boots to dry on his feet, with the result that he had painful abrasions on his feet.

Nellie had worked in a cable works, her hands and arms in a tank of water, and her skin tough with "rubber rash." There were rats in the works.

Robert had had his first symptoms at 15, not long before he had spent a great deal of time learning to swim in fresh water baths in a London suburb, the water to the bath coming from a reservoir which the boys used to visit regularly on Sundays, for the purpose of rat hunting.

Interesting as these are, however, I am fully aware that most of us have been in circumstances where we might be supposed to be exposed to infection—if infection it is—at some time or another, without developing disseminated sclerosis. Proof or disproof of the view put forward can come only from the bacteriologist. The rat and water theory of the etiology of disseminated sclerosis may end as a discarded theory, but it seems to me that this is enough suggestive circumstance in the bacteriology, geographical distribution, occupational incidence, and clinical findings to justify further work along these lines.

### SUMMARY

The occupations of 688 persons dying of disseminated sclerosis in 1925 have been investigated and the occupational death rate calculated where possible, the death rate for different counties of England and Wales have been worked out for that year, and the death rate for the years 1921-25 (corrected for age) is given. Clinically, 72 patients have been interviewed with regard to their exposure to rat-infested water.

### CONCLUSIONS

1 The findings of other workers as to heavy incidence in agricultural workers, wood workers, etc., have been confirmed. Incidence appears to be heavy also among painters, plumbers, moulders, and wool and cotton workers.

2 The high death rate in the fen district is analogous to the heavy incidence round the Great Lakes of America.

3 Clinical histories show some evidence in favour of the possibility that the infection of disseminated sclerosis is spread by rats and water.

4 No positive proof of the rat and water theory is yet available.

Finally I should like to say that I am grateful to the following, who have allowed me to see patients under their care: Dr. Browning, Alexander, Dr. E. A. Bennett, Dr. Davies, Atkinson, Dr. H. N. Hinderstle, Dr. N. Holthouse, Dr. E. D. Macnamara, Dr. J. G. Port, Dr. Philip, Dr. C. P. Symonds, Dr. R. C. Turnbull, Dr. F. M. P. Walshe, Dr. Wiggins, Dr. Woistell-Drought, and Dr. Yealland. I am also glad to express my indebtedness to the Registrar-General for allowing me to have access to the records, and to the authorities of Bethlem Royal Hospital, Guy's Hospital, and the West End Hospital for Nervous Diseases for giving me facilities for work in their wards or out-patient departments.

## A METHOD OF DRAINING THE SEPTIC UTERUS

BY

L. RIVINGTON HOBBS, M.D.,

MEDICAL SUPERINTENDENT OF ST. MARY ABERTS HOSPITAL CONSULTING GYNAECOLOGIST TO THE ROYAL BOROUGH OF KENSINGTON

To the class who are much engaged in the treatment of puerperal sepsis there is one form of treatment, at any rate, which is rapidly passing out of favour, and that is leaving the septic uterus to take care of itself. This opinion was definitely reached in this hospital when it was found that in over half the cases of puerperal sepsis admitted there was pent-up pus.

Since then it still seems to be a diversity of opinion as to the best method of draining the uterus if it is thought that a short account of that we have found most successful might be helpful to those engaged in the task.

The first point which always arises when we have to deal with pent-up secretions, naturally, from our surgical teaching is the question of placing a drainage tube in the part concerned. For some time a drainage tube was left in the uterus either as a continuous method or only for some hours. After considerable experience it became apparent that this was not the best form of treatment, as even after twelve hours the tube became offensive. It was thought that a tube left in the uterus acted as a sort of plug, or as a cork in a bottle, and retarded the flow of lymph from the tissues. In many cases it excited uterine contractions and even pain, because the organ is always tending to expel foreign bodies. Such a procedure exhausts the uterine muscle rendering it toneless and doing away with the very function it is essential to retain. In some cases we were of opinion that leaving in a tube promoted haemorrhage rather than lessened it, and dammed back the secretions in the uterus.

In order to arrive at the best method of draining the uterus two things have to be borne in mind. In severe cases the oedematous tissues of the uterus have to be drained, and in chronic cases the secretions in the over-distended tortuous glands have to have an exit. Further, the cervical canal must be kept clear of all foreign bodies and retained products, such as pieces of placenta membrane, and blood clot. The swollen cervical canal has to be reduced in size by a drug which diminishes the inflammation and so widens the canal.

In our experience the presence of a tube constantly in contact with the cervical canal does not obviously tend to reduce the swollen tissues. The whole art therefore, of draining the tissues, as well as regarding the patency of the cervical canal and the contractile power of the uterus, is to use a suitable drug without leaving in a tube.

In choosing a drug the question has to be asked. Is there a method which can be applied again and again without being followed by an increase in the fever or disease, so that each application fulfils the purpose of an aid to the draining of the tissues which are in a state of stasis which in no way injures the living cells of the tissues with which it comes in contact which promotes a flow of lymph from the infected tissues—a method which if properly applied, alleviates pain, relieves congestion and by so doing stops secondary haemorrhage mildly stimulates the uterine muscle to contract, and finally restores the function of the uterus? There is a method and that method involves the use of glycerin (undiluted).

*The Method*

The instruments required are (1) a catheter introducer, (2) terminal eved soft rubber catheters, (3) an anterior vaginal wall retractor, (4) a modification of Sims's speculum (5) 2 ccm and 10 ccm Record syringes.

No anaesthetic general or local, is necessary. The patient is placed in the lithotomy position. The external parts are washed with ether soap and water and then with saline. The vagina is treated in the same way. A Sims's speculum is introduced into the posterior fornix, and an anterior vaginal wall retractor into the anterior vaginal fornix and by a series of gentle movements the cervix is manipulated into a central position. The

speculum must not be pushed too far back, and the anterior vaginal wall retractor must be held horizontally and obliquely in the same plane. By this means a good view is obtained of the cervix, which becomes readily accessible for the purpose of passing a catheter. A terminal eved catheter is lubricated with glycerin, and gently inserted into the os, syringing the glycerin in front of the catheter so as to make a bed for its easy upward progress through the cervical canal to the fundus of the uterus. The syringing is still continued as the catheter is withdrawn. This is repeated if the uterus contains much pus.

*Modifications of Treatment for the Type of Uterus*

**After Labour or Miscarriage.**—The patients here are relatively insensitive, and the best time for treatment is certainly during the first few weeks following labour or abortion, and quicker results are obtained.

**Case, Following Labour.**—In the cases we have certainly found the undermentioned method the best in all our experience. Patients are prepared in the usual way, but after the insertion of the catheter into the uterus the anterior vaginal wall retractor and Sims's speculum are removed leaving the catheter in situ. The legs are then lowered on to the table and the syringe, with the catheter still fixed on the end, is placed on a sterile pad on the symphysis pubis. A pillow is placed under the knees to add to the patient's comfort. The assistant standing by the side of the patient, injects the glycerin slowly through the catheter, giving a slow irrigation treatment to the uterus. This may be continued for from twenty minutes to half an hour. In that time 60 to 100 ccm or even more glycerin may be injected without causing the slightest discomfort to the patient. This may be done twice a day. Undoubtedly a more thorough washing of the uterus is obtained, and in many cases after one or two irrigations the temperature has fallen by crisis, whereas the hot intermittent remedy which is used in the majority of cases has had no effect on the temperature.

**Chronic Case.**—Many patients required into the gynaecological wards have suffered from intermittent attacks of temperature, recurrent attacks of pelvic peritonitis and which have been so distressing to the patient, prolonged uterine haemorrhages. Many of our recent cases have been dealt with very successfully in the following way. Small quantities of glycerin have been injected into the uterus daily until the temperature has come down, and if there is still much discharge and erosion which is not cleared up the uterus is washed out occasionally with industrial methylated spirit under morphia gr 1/4. In cases of chronic haemorrhage as in chronic metritis and fibrosis uteri, patients are given an anaesthetic and the uterus is washed out alternately with methylated spirit and glycerin. This is repeated for about a dozen times. Subsequently in all cases the uterus is drained for the succeeding few days.

By these treatments many cases which have seemed quite hopeless have cleared up.

I wish to thank Dr. Mary R. Leach for her help in carrying out the treatment.

## CONGENITAL DEXTROCARDIA WITHOUT TRANSPOSITION OF OTHER VISCERA

ACQUIRED VALVULAR DISEASE AND ATRICULAR DILATATION

BY

DAVID KRESTIN, M.D. M.R.C.P. (LOND.),

MEDICAL FIRST ASSISTANT, LONDON HOSPITAL

Complete transposition of the viscera *situs inversus totalis* is too well known as a clinical condition to merit any special description. The following case, however, presents several features of unusual interest.

*Description of Case*

The patient, a female, aged 20, first came under the care of Dr. Theodoro Thompson in October, 1916.

**History.**—For ten years she has had a troublesome cough, shortness of breath on exertion, and attacks of palpitation

and faintness. There has been occasional pain across the right side of the chest in front, particularly after exertion. She has never had swelling of the feet or hæmoptyses. There was no history of rheumatic fever, chorea, or of other serious illnesses in childhood. As a child her heart was found to be on the right side.

The patient was pale, ill nourished, and underdeveloped woman. The lips were slightly cyanosed. The fingers were not clubbed. The pulse was small, completely irregular both in time and force, with a rate of 80 per minute. She was taking digitalis at the time of examination. The systolic blood pressure (brachial) was approximately 120 mm. of mercury.

On examining the chest, cardiac pulsation was observed to the right of the sternum, and the apex beat was felt in the fifth space, four inches to the right of the mid-sternal line. The cardiac dullness was found to the right of the sternum, the right border extending out to the apex beat.

FIG 1.—Radiogram showing heart shadow in the right side of the chest, and the aortic 'knuckle' to the right of the midline.

No thrills were felt on palpation. On auscultation the heart sounds were irregular, and over the apex beat both systolic and diastolic murmurs were heard. The second pulmonary sound was accentuated. The breath sounds over both bases were diminished, and accompanied by rhonchi and crepitations. The hepatic dullness was present in the normal situation, and the lower edge of the liver could just be felt beneath the right costal margin during deep inspiration. The urine was normal. The Wassermann reaction in the blood was negative.

The patient was radiographed by Dr. M. H. Jupe, to whom I am indebted for the following report (Fig. 1).

The heart shadow lies in the right side of the chest, with a small area projecting to the left of the spine. The aortic 'knuckle' appears to occupy a position to the right of the mediastinum. The heart is more globular in shape than usual, and its right margin is distinctly convex in outline. Although the pneumonchial shadows are more obvious than usual, gross abnormalities of the lungs or pleura is absent. The hepatic shadow is seen on the right side. A barium meal was given and the patient screened when the stomach was found to occupy a normal position. The case appears to be one of dextrocardia accompanied by transposition of the great vessels. The other viscera occupy a normal position.

The electrocardiogram (Fig. 2) is grossly abnormal. The abnormality of waves in Lead I makes it difficult to be certain of their direction, on the whole they do not appear inverted, P waves are absent in all leads, and the ventricular complexes, many of which are ectopic, are quite irregular.

#### Diagnosis.

There can be little doubt as to the diagnosis in this case. The patient has congenital dextrocardia with normal

position of other viscera, and this is associated with a valvular lesion, probably mitral stenosis due to old rheumatic endocarditis. The case is complicated by auricular fibrillation.

#### Comments.

Congenital dextrocardia without transposition of other organs is comparatively rare. In 1921 Lambry and Pizzi<sup>1</sup> collected from the literature twenty-nine cases of this condition in which the diagnosis was certain, whereas they were able to collect 227 cases of total transposition of viscera.

The appearance of the aortic 'knuckle' to the right of the midline in the radiogram is unusual in this type of case. According to Lambry and Pizzi the cardiac chambers are not actually reversed in congenital dextrocardia without total situs inversus. They hold that the condition is due to a 'pulling over' of the heart without rotation, and thus the relative position of the great vessels shows little departure from the normal. For this reason the curves in Lead I of the electrocardiogram are usually not inverted as in complete transposition of viscera. Several cases of undisputed diagnosis have, however, been described, in which the cardiac cavities were actually reversed (Moffett and Nienhot, Goiter,<sup>2</sup> Meyer,<sup>3</sup> Capon and Chamberlain<sup>4</sup>). That the functional left heart is on the right side in this case is further suggested by the fact that abnormal murmur, presumably mitral in origin, was heard over the apex beat.

FIG 2.—Electrocardiogram showing auricular fibrillation (absence of P waves), and gross abnormality of ventricular complexes in Lead I.

in the fifth right space, and by the shape of the right border of the cardiac shadow in the radiogram (Fig. 1). In the electrocardiogram (Fig. 2) also described, one cannot be certain of the direction of the waves in Lead I as they are so abnormal. It would certainly be unusual to find the waves in Lead I normal in direction in a case where the cardiac chambers are actually reversed. A case of congenital dextrocardia without transposition of other viscera, however, was described by Gutic and Covert<sup>5</sup> in which radioscopically the cardiac cavities and great vessels appeared reversed, but in which the electrocardiogram was normal. The diagnosis in this case was not confirmed anatomically.

The coexistence of acquired valvular disease and congenital dextrocardia is by no means unknown. So far as I am aware, mitral stenosis associated with congenital transposition was first described by Owen<sup>6</sup> in 1911. Other cases complicated by valvular disease have since been described, indeed, an individual with congenital dextrocardia would appear to be as much liable to rheumatic disease as any other.

Curiously enough, abnormalities of cardiac rhythm are apparently very rare in this condition, but there are a few too few electrocardiographic records of these cases to justify any definite statement. That interference with the conducting mechanism may occur is illustrated by such records as those published by Parsons Smith<sup>7</sup> and Potts and Ash<sup>8</sup>. Auricular fibrillation complicating dextrocardia, as in the case here described, however, must be extremely rare, I could find no reference in the literature to a similar case. Lambry and Pizzi state that they have never seen auricular fibrillation occur in this condition.

concentric heart disease and this was also the experience of Parkinson and Clark-Kennedy\* in 1926

I am indebted to Dr Theodore Thompson for kindly allowing me to publish this case, and to Dr John Parkinson for the electro-cardiographic record

## Memoranda.

## MEDICAL, SURGICAL, OBSTETRICAL

## ENLARGED RIGHT OVARIAN CYST

In view of the rarity now of extreme abdominal enlargement due to an ovarian cyst the following details and illustration of such a case may be of general interest

A woman aged 57 was admitted to hospital as a case of acute intestinal obstruction there had been no movement of the bowels for three days. She complained of generalized pain over the abdomen and in both legs which had lasted only a fortnight. There was no urinary trouble. The menses had occurred as usual every seven years previously. Menstruation had always been normal. The abdomen had been increasing in size for about twenty years. She had consulted a medical practitioner twelve years prior to admission but he had refused to operate.

The abdomen was enormously distended with large veins coursing over it. The swelling gave a remarkably distinct fluid thrill but the flanks were clear so a cyst was excluded. An ovarian cyst was diagnosed. Both legs were purple up to the knees and cold to the touch. There was dry gangrene of the toes of both feet. The patient said that she had not been able to go to bed for more than six months. She spent the time sitting in a chair. Under a local anæsthetic I cut down to the peritoneum and then passed a few stitches through it and the wall of the cyst. A trocar and cannula were thrust into the cyst and a No. 3 catheter was inserted. The patient was drained very slowly

for two days and then a large catheter was introduced. At the end of four days her legs down to the toes resumed their normal colour and became much warmer. The pain which had been present ceased. The patient could then be put to bed. The fluid which came away was of a dark colour. Each measurement of it was checked by two senior nurses. At the end of a week 103 pints of fluid had been removed. Some little fluid was still retained but the patient was getting weaker so that the catheter was withdrawn. She died a fortnight after admission. At the necropsy an enormous ovarian cyst was disclosed. There was no free fluid in the abdomen. The liver was almost unrecognizable in shape it resembled a crescent.

I do not like to publish this case my thanks are due to Mr A C Bate surgeon to the Royal Sussex County Hospital  
 H H BURNETT M.B. Ch.B.

TRAUMATIC RUPTURE OF THE DUODENUM AND  
LIVER SUBPHRENIC ABSCESS RECOVERY

The following case is placed on record on account of the rarity of recovery after such an accident and indeed of the condition itself.

A woman aged 30 when riding a motor cycle at night crashed into a motor lorry. He was admitted to Mr A B Mitchell's ward in the Royal Victoria Hospital Belfast on August 25th 1927. When I saw him some five hours after the accident he was suffering from shock and writhing with abdominal pain. The abdomen was rigid and tender especially to the right of the middle. In about the tip of the tenth rib it was somewhat tympanitic and distended.

I opened the abdomen by a right paramedian incision and found a large amount of blood coming from an extensive tear in the under surface of the liver after mopping out the blood intestinal contents were seen well up from the duodenal region. I found a ragged tear far back on the anterior surface of the first part almost at the angle of junction with the second. I sutured this with one difficulty as the patient was very stout. The hole was the size of a turrepony bit and was more or less circular but there was no induration thickening or any evidence of ulceration.

I then made a rapid survey of the small intestine to exclude other perforations. It revealed numerous bruises but no tear. His condition did not permit of further interference so I closed the wound leaving a pack down to the ruptured liver to control bleeding and a drain.

He caused some anxiety for a few days and developed a moderate degree of wound sepsis but had no vomiting. By September 4th the temperature was normal and remained so until September 10th when it began to rise at night. This continued until October 5th and he was complaining of left-sided pain when I then saw him. I explored the left subphrenic region and found pus. Next day Mr Mitchell helped me to open a very large subphrenic abscess after subperiosteal resection of the twelfth rib. The patient then made steady progress towards recovery although his pulse rate was 120 for a long time. He left hospital in good health except for a ventral hernia on November 12th. He had no gastric symptoms either before or after the accident.

Berry and Gumpert record 23 cases in the ten principal London hospitals prior to 1907 all the patients died. Choyle states that only 5 such patients were admitted to the London Hospitals from 1899 to 1919 and all died. Rowlands (British Medical Journal 1923 i 716) records 23 cases of ruptured duodenum out of 381 of ruptured intestines, but does not give separate mortality.

B.M.S.

C J A WOOD M.D., M.B., F.R.C.S.I.

GANGRENOUS APPENDIX IN A STRANGULATED  
HEPATIC SAC

The following case of strangulated inguinal hernia seems sufficiently rare to merit description.

An infant aged 6 weeks was admitted to Booth Hall Infirmary on September 15th 1927. The mother stated that she had noticed a swelling in the right groin the day before when it was tender and increased in size. The child was restless but had no vomiting. The bowels had been opened the day before.

On admission the temperature was 97° and the pulse rate was 140. The right side of the cranium was swollen tense and discoloured and the cord on the same side was thickened. The mass was irreducible.

At operation a distended sac was found strangulated by a tight external ring. Inside the sac was the appendix which was completely gangrenous together with the lower pole of the caecum which was engorged and discoloured but still viable. The lumen of the caecum and the ileo-caecal junction were outside the sac a fact which probably accounted for the absence of vomiting. The appendix was removed and the sac ligatured.

The child recovered well after operation but unfortunately died eleven days later from enteritis.

Booth Hall Infirmary, Manchester

## CONGENITAL DIAPHRAGMATIC HERNIA

It may perhaps be worth while to add this to the long list of such cases on record.

On November 8th I was called to see a newborn infant. The nurse informed me that when the baby was delivered she noticed the face to be intensely blue and she completed delivery at once. The apex beat was on the right side. She tried artificial respiration for some time and as there appeared to be no sign of improvement he sent to me.

When I arrived the infant had been born about thirty minutes. The face was almost blue black the abdomen was distended and tense and the apex beat was at the right nipple. The rate was about 30 and every fifteen seconds or so the infant took a short jerky inspiration. It lived about fifteen minutes after my arrival.

At the post-mortem examination the heart was seen to occupy the right side the right lung lay above it and was very slightly inflated. The left lung was infarcted and the left side of the thorax was packed with coils of intestine. The liver was swollen and congested and occupied practically the whole of the right cavity. The hernial opening was in the left posterior quadrant and its edge was very smooth.

I took a specimen from Dr Cavendish Fletcher who was good enough to make the following report.

The posterior part of the left side of the diaphragm had failed to develop leaving a hole about three-quarters of an inch in diameter. The posterior side of the bowels was found in the posterior abdominal wall and the anterior abdominal wall was a sort of a cleft edge quite smooth and of even thickness.

to trauma. The stomach was in its normal position, and the perforation of the diaphragm by the oesophagus was normal. The liver was large and weighed 7 oz. It was congested. The extreme tip of the left lobe was turned up into the thorax through the diaphragmatic perforation referred to, a marked indentation of this lobe indicating the position of the edge of the hole in the diaphragm. The whole of the small gut and the ascending and transverse colons occupied the left side of the thorax. The spleen, too, was found in the thorax, lying in the middle line, just in front of the tiny undeveloped left lung. The latter weighed only 4 grams, having failed to develop beyond this size owing, no doubt, to the pressure of the displaced viscera. The right lung was normal, but unexpanded. It weighed three-quarters of an ounce. The heart was completely displaced to the right side, but was otherwise normal. Apart from the hernia, and the failure of the left lung to develop, no visceral disease was found.

Assuming the condition had been diagnosed *ante mortem*, it would be interesting to know what chances of life the child would have had if the hernia had been reduced by open operation.

Hayes, Middlesex

D. H. WALDROV, M.B., B.Ch.

### CHRONIC VINEGAR POISONING

The following case seems worthy of note, on account of the paucity of recorded cases where commercial vinegar has been consumed over a considerable number of years in much the same quantity as the other more refreshing beverages which are indulged in by the world at large.

In August, 1927, I was called to see a woman aged 60. She was in bed, looked ill, but was mentally bright and alert. Beside her stood a quart bottle of vinegar three pints empty. This quantity she acknowledged she had consumed during the same day. I learned from her relatives that this was about her usual daily ration, that, in fact, she never ate anything without washing it down with a liberal quantity of the liquid. This had been her habit for as many as thirty years. At one time she had weighed 112 lb., now her weight was 38 lb. Till a week before she had been up and about the house, but during the last five weeks she had taken no food, nevertheless she had not decreased her daily quantity of vinegar. Her temperature was subnormal, her hands and forearms and her feet and legs were almost black. She had no pulsation in the arteries below the elbow and knee. The apex beat was easily palpable in about its normal position, and the heart sounds were clear. She was most emaciated, but no signs of malignant disease consistent with such an advanced state of emaciation could be discovered. She had some difficulty in swallowing, but this appeared to be due to general weakness. The urine was acid, but contained no abnormal constituents.

She was admitted to the Royal Salop Infirmary, but could retain nothing by mouth or by rectum, and died within forty-eight hours.

An inquest was held, and the verdict that death was due to a chronic intoxication (the intoxicant being commercial vinegar) was pronounced in by the coroner (Dr. Curdson), the resident physician (Dr. Evans), and myself. For the following notes on the *post-mortem* examination I am indebted to Dr. Evans of the Royal Salop Infirmary.

Deceased is a most emaciated woman there being an almost complete absence of naked eye fat. The tongue shows a chronic superficial glossitis and the pharynx a chronic pharyngitis. The oesophagus is normal. The stomach is dilated, its mucous membrane very white, smooth and non-rugose, and contains clear fluid. There is some intestinal catarrh. The kidneys are small and pale. The left testis is small and shows a small amount of fatty degeneration. The lungs show atrophic emphysema, chronic bronchial catarrh. The spleen is small and normal. The liver is of the well marked nutmeg type and shows no pathological changes. The gall bladder is distended and full of bile.

It appears remarkable that the woman lived so long. The state of acidosis was evidently prevented by the formation of acetate salts, which were in turn broken down, but the condition of her digestive organs gradually became worse till they reached a state of complete abrogation of function. She was, in fact, as nearly as possible pickled alive.

Shrewsbury

## Reports of Societies.

### EXTENSIVE AORTIC ANEURISM

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland on December 5th, 1927, President, Dr. T. T. O'Farrell, in the chair, Dr. A. R. J. Dunagan read notes on a case of aneurysm of the aorta, and showed a specimen.

Dr. Dunagan said that the entire thoracic aorta was moderately dilated, and beyond the transverse portion of the arch was filled with a mass of laminated clot, leaving only a small lumen. There was advanced atheroma, but no microscopic signs of syphilis. Microscopically, however, there was found infiltration of the media and adventitia by mononuclear cells, and there were patches of scar tissue in the media. The Wassermann test was strongly positive.

The President said that aneurysms of the aorta were rarely seen, since these cases were not usually admitted into general hospitals. The symptoms were sometimes not very clear. Dr. J. Lutz said that he had never met a case in which there had not been a positive Wassermann reaction.

Dr. William Whelan said that he had operated upon three cases of aortic aneurysm, one man was alive and well seventeen years later. At the time of operation the aneurysm was thin walled, and appeared likely to burst when the abdomen was opened. The introduction of wire had produced in this case a complete cure. In a second case a necropsy had been performed some four years after the introduction of wire. In this case the aneurysmal portion was also completely consolidated, but the man died from rupture of a secondary dilatation. The third patient died shortly after the operation. Dr. W. D. O'Keefe said that he had never seen such an extensive aneurysm, the patient must have suffered from remote syphilitic aortitis.

Dr. John Moore referred to a description of aneurysm or the aorta which stated that aneurysms of the ascending aorta provided physical signs, while aneurysms of the descending aorta were indicated by symptoms. He feared that at present there was a tendency to attach too great confidence to diagnoses made by x-ray examinations. Dr. H. B. Goulding mentioned the case of a woman who had died suddenly while carrying a bucket of coal upstairs. She had complained of persistent cough and pain in the chest. Dr. Goulding found an aneurysm adherent to the sternum, it had apparently burst into the pericardial cavity. Dr. A. R. Parsons discussed the auscultatory signs in interthoracic aneurysm, and thought that there were quite a number of these cases in which there was no murmur present.

Dr. Dunagan, replying, said that in the Johns Hopkins Hospital there had never, he believed, been a case in which it had not been possible to disclose a syphilitic lesion microscopically. In the present case no aneurysm had been present.

### Malignant Papilloma of Kidney

Dr. T. T. O'Farrell showed a malignant papilloma of the pelvis of the kidney of a man aged 54. Three months previously the patient had felt a stabbing pain in the left side, he had never passed blood, but the urine had been colored red. On admission pain was present at the lower border of the ribs at the back, and was increased by coughing. A swelling was felt in the left lumbar region and projected into the left iliac fossa. It moved with respiration and was dull on percussion, except for a band of resonance which crossed it. The left kidney which was removed, measured 15 by 9 by 7 cm., it was highly lobulated and one surface showed many adhesions. It was almost completely cystic, due to back pressure. The whole pelvis was occupied by a papillomatous mass, unlike a villous papilloma of the bladder, which appeared to have its origin at the attachment of the pelvis to the kidney proper, though the growth extended to a certain extent into the cystic spaces. Microscopically the tumour was composed of stalks of fibrous tissue covered by a layer of transitional epithelium. Mitotic figures were fairly numerous, and though no definite metastases were

tissues could be seen the evidence of rapid growth suggested the probability of malignancy.

#### Differential Diagnosis of Uterine Tumours

Dr D C MUIR showed a uterine tumour removed from an unmarried woman aged 76 following slight but persistent vaginal discharge, she had had a severe haemorrhage. Dr Muir found the vagina filled with a clot, and there was a small papilloma protruding from the cervix, which was very big and felt sore. Dr Muir thought that it was probably a case of adenocarcinoma and in the course of a few days performed complete hysterectomy. The patient did well.

Dr J T WIGHAM said that the tumour was a particularly uncommon one, the cervix was larger than the body of the uterus. Such tumours nearly always involved the body of the uterus and not the cervix. The present growth had probably started in the body, and then extended to the cervix. It was an adenocarcinoma of "cushion" growth. It was always recognized that these tumours were either actually or potentially malignant somewhere in them there was a very definite infiltration of the muscular wall of the uterus, but in this case he had been unable to find this though there was papillomatosis of the mucous membrane of half the body and the whole of the cervix. Dr Wigham thought that it was benign in origin, but was tending to become malignant. It was always a debatable point whether these tumours began as cancer and developed papillomatous growths or began as papillomas and became malignant. He did not think that the growth in these cases extended any further into the wall of the uterus than the glands of the normal endometrium.

Dr P J ROWLETTE suggested that this tumour might be endocervical in origin and arise from the mucous glands. He said that malignant disease was very seldom seen in so old a patient.

Dr J LAIR said that when he had first seen the specimen in the laboratory he had considered it malignant but when he had prepared section he had realized that it was apparently benign. He had not met with this condition before except in the examination of curettings. These tumours originated often from the endometrium of the body of the uterus and rarely from the mucous membrane of the cervix. Inasmuch as they resembled the villous papilloma of the bladder, both in structure and from their tendency to malignancy he thought that the term villous tumour of the endometrium suggested by Sir John Blund-Sutton was most appropriate. He was not convinced that there was no infiltration of the uterine wall and agreed that hysterectomy in this particular case was the ideal treatment.

The President thought it very difficult to say whether cancers grew from the tubules in the cervix when the tumour was superficial. It would have been difficult to find infiltration in this case since the uterus was very old and fibrotic. He asked if any mitoses had been found.

Dr MUIR replying, said he had had no doubt from the clinical symptoms that this patient had malignant disease, and that it was essential to do a complete hysterectomy.

Dr WIGHAM replying said that there were no mitoses and that his reason for concluding that this was a tumour of the body rather than of the cervix was that papillomatous tumours of the body were much more commonly met with than tumours of the cervix.

#### James Exhibit

Mr W PEARSON read notes on a case of hydronephrosis and Dr J T WIGHAM showed the specimen. The patient a woman aged 45 underwent curetting three years previously and a laparotomy for uterine and pelvic trouble. The right ovary and tube were removed and suspension opeia on performed. At that time it was noted that the uterus was enlarged and adherent to the rectum and the c were also adhesions in the right adnexal region. Two and a half years later she began to suffer from stiffness and pain in the upper abdomen which spread to the right loin and sometimes into the back. At times when the pain was severe vomiting occurred and was followed by relief. There were no urinary symptoms and the urine was normal.

Laparotomy revealed a firm, rounded somewhat tender tumour, the size of a tangerine orange in the right epigastrium just above the umbilicus, and a second swelling was felt which was evidently an enlarged kidney. The bladder and ureteral orifices were normal. Urine was coming from each but in considerably less amount from the right ureter. A hydronephrotic kidney with a tenaciously distended pelvis and an enormously dilated and tortuous ureter was removed. The symptoms which were entirely despective and suggestive of duodenal trouble, were evidently due to duodenal distortion or kinking produced by the greatly distended renal pelvis. There seemed little doubt that the pelvic portion of the ureter became involved in scar tissue subsequent to the gynaecological operation, with resulting chronic partial obstruction to urinary flow.

Dr J A MCGATH read notes on cases of four tumours of the neck, and exhibited specimens. The first was an alveolar sarcoma of the parotid. It consisted of malignant spheroidal cells irregularly divided off into islands by fine bands of fibrous tissue. The islands varied in size, and the specimen bore a close resemblance to a mixed sarcoma and enchondroid carcinoma of the breast.

The second exhibit, a primary sarcoma of a lymph gland in the neck was from a man, aged 52 who had had a lump on the side of the neck for about twenty years. It slowly grew in size, was egg shaped, slightly movable, and not adherent to skin though the adjacent glands were slightly enlarged. The specimen consisted of a somewhat ragged piece of tissue not unlike a mass of lymphatic glands with considerable fibrous tissue and some golden coloured pigment. There was also a separate piece of tissue, resembling a lymphatic gland solid in consistency and of pale colour. On section it was found to be composed of malignant spheroidal cells in places collected in masses but elsewhere surrounded by fibrous tissue. Mitotic figures were very numerous. There was a very small amount of lymphoid tissue present probably the remains of the original lymphatic gland but no tendency to the formation of acini was evident. There were patches of necrosis in some sections but no similarity to endothelioma.

The third exhibit was a secondary carcinoma of a lymph gland in the neck, the secondary growth being larger than the primary, and the last a carcinoma from the anterior triangle of the neck.

Dr J LAIR read notes on a case of carcinoma of the stomach and showed specimens. A ray examination showed a dilated oesophagus the barium being longer retained than normally and passing very slowly into the stomach. There was constriction of the oesophagus near the cardiac end of the stomach with a large filling defect of the lesser curvature and an irregularity extending upwards to the cardiac orifice. The patient could take nothing except liquid foods and eventually died apparently from exhaustion. The entire stomach except the pylorus and about 2 in. of the stomach adjacent to the pylorus was found to be occupied by an ulcerating fungating and in many places necrotic tumour, which surrounded the cardiac orifice causing incomplete obstruction. There was no stenosis of the pylorus. The walls of the stomach were greatly thickened. On the anterior wall the ulceration had excavated a small area about the size of a sixpence which was only covered by inflamed peritoneum. The posterior wall was adherent to the pancreas which was penetrated by the tumour. The tumour lay spread along the lymphatics and had involved the spleen which was drawn towards and was adherent to the stomach. The regional lymph glands were involved and one secondary deposit the size of a walnut was found in the left lobe of the liver. Microscopically the tumour was a rapidly growing adenocarcinoma. Mucoid degeneration was found in the primary and secondary foci.

#### JAMES MACKENZIE INSTITUTE

##### Gastric and Duodenal Ulcer

At the James Mackenzie Institute for Clinical Research, St Andrews Professor ARCHIBALD YOUNG (Glasgow University) read a paper, on November 22nd, on some surgical aspects of gastric and duodenal ulcer. Professor Young

began by referring to a previous statistical study from his clinic into the efficiency of present-day methods of diagnosis of ulcers of the stomach and duodenum, and into the value of gastro-jejunostomy in their treatment. The diagnostic error had been found to be small, and to depend, not upon any fault in the methods, but upon erroneous deductions from the data which they provided. In this series 66.6 per cent of patients had made a complete recovery after gastro-jejunostomy, while 83 per cent had been greatly or considerably improved. The operation performed was the usual posterior anastomosis, without pyloric exclusion. The further series upon which the lecturer's present paper was based included 146 cases, of which 12.3 per cent were gastric, 28.08 per cent duodenal, and 59.59 per cent pyloro-duodenal. Of these, 130 had occurred in males, 24 in females, and in 8 males the location of the ulcer was doubtful. Professor Young emphasized his belief that many pyloro-duodenal ulcers, although often classified as gastric, had more in common with true duodenal ulcers than with those of the gastric type. He still performed gastro-jejunostomy as an almost routine operation for peptic ulcer, and found it especially valuable in duodenal and pyloro-duodenal cases. In his experience pneumonia was the chief cause of death, and he thought that its incidence might be reduced by careful nursing and, since the condition was often of embolic origin, gentleness in handling the ulcerated segment. The therapeutic effect of gastro-jejunostomy was due to a combination of factors, of which drainage and access to the stomach of the alkaline contents of the duodenum were important. It was unnecessary to occlude or divide the pylorus to ensure relief. Excision of the ulcer was generally valueless, unless combined with some method of securing gastric drainage. Plastic operations at the pylorus were no more efficacious than simple gastro-jejunostomy. Gastrectomy is reserved for large and adherent gastric ulcers, believing that so severe an operation was seldom justifiable for more limited lesions. Partial gastrectomy did not eliminate, though it might lessen, the risk of recurring ulceration. He then outlined the work of Roscnow, Mann and Williamson, and others on the selective affinity of certain strains of streptococci for the mucosa of the stomach and duodenum, and referred to the discovery by Kodama of a direct lymphatic connection between the wall of the gall bladder and that of the duodenum, also to Wilkie's recent observations. With regard to treatment of perforated ulcer great advance had been made in the speaker's lifetime. Much of this was due to Murphy, who had consistently taught rapidly in operating and the minimum of interference. Gastro-jejunostomy was rarely required either at the primary operation or later, as Nature was able to correct a considerable degree of the narrowing which might follow the infolding of the ulcer. Professor Young preferred to drain the ulcer of perforation locally. In diagnosis, most stress should be laid on the patient's history. Clinical and laboratory tests helped much but interpretation of the results of x-ray examination was very liable to error.

At a meeting of the Manchester Pathological Society on December 14th, with the president, Mr F. H. Worswick, in the chair, Dr W. SUSMAN read a paper on the relation of the spleen to immunity. Dr Susman referred to the work of many observers, which had indicated that the reticulo-endothelial system, and the spleen in particular, were concerned with the production of immune bodies. He thought it might be assumed that the pulsations of the spleen afforded an indication of its function. These pulsations, as shown by Schiffrin, were inhibited by atropine and augmented by injections of brain extract. In a small series of rabbits the subcutaneous injection of a boiled watery extract of brain tissue had enhanced the process of agglutinin formation against *B. typhlosus*. The administration of the same extract to a large series of mice infected with pneumococcus type I had shown a survival of 51 per cent of a total of 262, while an equivalent number of control animals had died. The survival extended over two to three weeks, and, in several instances, up to five to eight weeks, when the experiments were concluded.

## Reviews.

### URINARY DISEASES IN CHILDREN

A volume on affections of the urinary tract in children, by Professor Nobe-court of Paris, is the fourth of a series of clinical studies, all written by him and derived from his hospital practice and teaching. The plan of the present volume follows strictly that of the three preceding, its chief feature is the presentation of individual cases with their special history, symptoms, signs, course, and treatment, accompanied by a commentary that connects their peculiar manifestations with the general aspects of the disease. Of the 350 pages that make up the present volume about two-thirds are devoted to various types of nephritis in children and infants. These types are at first presented on a clinical basis, according as oedema, haematuria, or a high blood urea is the predominant feature, but the classification is not rigid, a good many examples of mixed types are given, and the occurrence of acute, subacute, and chronic cases is illustrated also. These case records show how often mixed types occur, also that definite haematuria is a common feature of nephritis in children, and that apparently complete repair of the kidney tissues may occur, even in prolonged and severe cases. Two interesting chapters deal with cases of nephritis complicated by purpura and by convulsions, and the relation of nephritis to infantile diabetes is also illustrated by a striking case. In the records of the cases special attention is given to the dimensions of the heart and liver, and to the blood pressure and the blood urea, these observations being often shown as graphic curves and outline diagrams. Other chapters in this admirable clinical repository deal with pyelitis and pyelonephritis, orthostatic albuminuria, paroxysmal haemoglobinuria, malignant renal tumours, bladder calculus, and waxy disease. In this collection of full and accurate case records Professor Nobe-court has made a valuable contribution to a difficult subject, and although in his discussions of the cases he does not attempt any general or systematic statement of the pathology of nephritis—this, indeed, being beyond his present aim—he provides valuable material towards such an end. This kind of book, an incorporation of case records with commentary, is of greater value to the practitioner of some experience than to the student, and it is a kind of medical writing in which success can only be achieved by one experienced both in the practice and teaching of medicine. Professor Nobe-court has this twofold experience in a high degree, and in this series of clinical studies he conveys to his readers almost as vividly as he does to his hospital classes his gifts as physician and teacher.

### BASAL METABOLISM IN DISEASES OF THE THYROID

The volume under review is entitled *Clinical Investigations into the Basal Metabolism in Diseases of the Thyroid Gland*. It takes the form of a Supplement to *Acta Medica Scandinavica*, and is, in effect, an abridged and in some respects an elaborated English translation of a treatise by Dr EGERT MOLLER, first published in Danish in 1925. The greater part of the work is concerned with the problem of Graves's disease. The author, finding that "in the literature proof was not furnished for the general opinion that Graves's disease is always accompanied by increased basal metabolism," undertook an elaborate clinical and laboratory investigation of the problem. The questions which he has attempted to answer are (a) the relation between the amount of basal metabolism and the occurrence of clinical symptoms, (b) the value of basal metabolism determined in diagnosis and prognosis, and (c) the effects upon basal metabolism of different kinds of treatment. The critical work in the literature is rejected as defective through

<sup>1</sup> *Clinique Medicale des Enfants, Affections de l'Appareil Urinaire*, par P. Nobe-court, Paris, Masson et Cie, 1927. (Med. 36, 11, 13, 57 figures, 40 francs majoration.)

*Clinical Investigations into the Basal Metabolism in Diseases of the Thyroid Gland*, By Egert Moller. *Acta Medica Scandinavica*, Supplementum XVI, Copenhagen, Levin and Munksgaard, 1927. (Med. 37, 219, 15 figures.)

of clinical trial and a precise definition of what constituted Graves's disease in the subjects studied. Moreover, there was not sufficient appreciation of the necessity for repeated determinations in order to obtain true basal values. The method employed by Dr. Moller was that of Krich, which with certain precautions which are discussed in detail, is well adapted to clinical employment. As a result of 106 determinations on 34 different normal subjects it was concluded that a deviation of 10 per cent from the standard basal metabolism, calculated from the standard values of Benedict and Harris for the weight, size, and sex of the subject was to be regarded as in all probability pathological. Some 89 cases of Graves's disease were then studied. The clinical records are omitted but may be found in the original Danish edition. Only those cases exhibiting goitre, tremor, and permanent tachycardia are regarded as cases of true Graves's disease. For these the basal metabolism was found to vary from 93 to 190 per cent of the normal, nine cases out of ten giving values above 110 per cent. The frequency of the symptoms is placed in the order: tachycardia, tremor, goitre, nervousness, increased basal metabolism, palpitation, sweat secretion, and exophthalmos. It is concluded that a basal metabolism lying within normal limits does not exclude the presence of the true disease. Treatment by x-rays and by resting and overfeeding led to a fall in the basal metabolism but usually the subjective symptoms disappeared first. In 50 per cent of the cases x-ray treatment led to definite improvement or even cure. It is suggested that cases not responding to x-rays should be immediately operated upon.

Turning to other thyroid conditions it was found that almost without exception cases of simple goitre gave normal basal metabolism values. On the other hand every case of myxedema gave a low value. The lowest was never less than 60 per cent of the normal—a level which was consequently taken to represent that attained when there is complete functional inactivity of the thyroid. The effect of thyroid treatment was always to cause a rise towards normal basal metabolism but the maximum effect was not attained for two to eight weeks. This rise is an early symptom of mitigation of the condition; it generally precedes the disappearance of the subjective symptoms. The author engages in a discussion of the principles and practice of thyroid treatment. This extensive report contains full protocols and elaborate analyses of the laboratory data which are certainly the most comprehensive available on the subject.

### THE RAPID EXPERIMENTAL AND PRACTICAL

This first volume of a German textbook of practical therapy as the result of experimental investigation, edited by Professor R. von den Velden and P. Wolff was reviewed in our issue of December 11th, 1926 (p. 1125). It dealt with the general principles of therapeutics; the second volume, which has now appeared, discusses the application of these principles in disease. It contains forty-eight articles by some thirty different authors but Professor von den Velden is the chief contributor for he has written eleven articles. The contributions vary in merit and it is possible to mention a few only.

One of the most interesting is Professor Frank's article on diabetes mellitus; it concludes with a short account of synthetic therapy. Dr. Richter writes briefly and in a cautious tone on endocrine therapy. He concludes his summary of the various methods of testicular therapy with the words "Unfortunately rejuvenation is at present only a pious hope." He considers however that ovarian therapy may give positive results. His article provides an example of the unfortunate slowness with which knowledge passes from one language to another for he ascribes to Laqueur and Zondek the discovery of the ovarian hormone "folliculin" or oestrin and does not mention the previous work of Allen and Doisy.

The article by Dr. O. W. Gross on the therapeutics of diseases of the alimentary canal is a very good summary.

Other articles deserve mention because they deal with subjects often omitted from ordinary textbooks of medicine. Such are the articles on the treatment of drug habits (Dr. P. Wolff) on psychic therapy (Professor J. H. Schmitz) and on the treatment of insomnia and of pain (Professor H. C. Hermann).

Enough has been said to indicate the general scope of the book. The aim of the editors was to set forth a system of rational therapeutics founded on the basic sciences of physiology, pathology and pharmacology, and bacteriology and they deserve great credit for making so courageous an attempt. This second volume may be regarded as a summary of the present state of therapeutics and as such presents certain points of interest. For one thing a comparison of the various articles shows very clearly how much advance has been made. In certain articles—such as those on diabetes mellitus and on gastric and thyroid disease, the contributors can describe fairly exact rules of treatment based on physiological principles. The same can be said regarding the treatment of diseases due to spirochaetes and trypanosome. But in many of the articles describing one of the commonest diseases the writers can only give general directions for symptomatic treatment which are much the same as were employed fifty years ago.

It would of course be irrational to expect a uniform advance in medicine but the failure of certain sections to make any appreciable move forwards is very striking. Yet it is indeed a hopeful sign that such a work as that before us has been produced. No one will suggest that the present output of medical literature is inadequate in volume but that attention is directed to the diagnosis or aetiology and to pathology and an attempt to produce a general account of the treatment of disease based on scientific evidence is not welcomed; it only as a stimulus to research in the more neglected fields of therapeutics.

### MEDICAL ENTOMOLOGY

The London School of Tropical Medicine has already published six volumes of memoirs relating severally to Fiji, Ceylon, Egypt, Western Pacific, the Caribbean and Southern Rhodesia, and in continuation of the series the London School of Hygiene and Tropical Medicine has now issued its first memoir on *Isaulele in Polynesia and Melanesia*. The work is by Dr. P. R. Buxton, director of the department of entomology, assisted by Mr. C. H. E. Hopkins and relates principally to medical entomology, including climate as being a part of the environment in which the insect lives. In a subsequent publication the author proposes to recount his investigations into filaria and other matter which relate to human beings. The visit to the south-western Pacific which lasted throughout the years 1924-25 was undertaken with a view to co-operating with the New Zealand Government and its local administration and department of health in the study of filaria is the principal programme was that special studies should be made on the mosquito which carries filaria and that an attempt should be made to reduce the number of the mosquitoes in this particular region.

The volume contains a mass of carefully observed facts which are not only interesting in themselves but which will be invaluable to those who propose to carry on researches in the regions concerned. Although the mosquito *Aedes (Stegomyia) triseriatus* the vector of filaria was the main object of investigation the author has properly included the whole of the insect fauna of the district in his researches as being the natural setting in which to regard *Aedes* itself. Several species of *Aedes* are known to *triseriatus* being the carrier of malaria and of this species there are several races or varieties each of which has a fairly definite and limited distribution in the islands of the south-western Pacific. The life-history, geographical distribution, habits and morphology of these varieties have been fully worked out and described by Dr. Buxton with

\* *Handbuch der Praktischen Therapie der akuten Infektionskrankheiten* (Herausgegeben von Prof. Dr. R. von den Velden und Prof. Dr. P. Wolff). Band I. Erste Hälfte. Leipzig, J. A. Barth, 1927. (Sixteen 8vo. English plates, 388, 22 figures. Zweite Hälfte 1927. 65, 22 figures. 1/3 the two parts.)

\* *Isaulele in Polynesia and Melanesia*. Part I. By Dr. P. R. Buxton and Mr. C. H. E. Hopkins. London, School of Hygiene and Tropical Medicine, 1927. (Cr. 17, 31 + 60, 1 plate, 32 plates, 10 col.)

the addition of diagrams to assist in their diagnosis. In discussing the question of the control of these insects, he explains that no work directed against the one disease-bearing species can be effective unless general anti-mosquito measures are also prosecuted vigorously, because the success of such a campaign depends largely on the help of the mass of the population. Natives will not be induced to believe in the efficacy of anti-mosquito measures which leave the irritating, night-biting *Culex fatigans* and the virulent *Aedes aegypti* in undisturbed activity. Referring to control measures in such a district as the Apurimac municipal area in Simor, where the medical department co-operated during a period of six months in an attempt to reduce the number of mosquitos, it is stated that *Culex* could be readily dealt with by such simple measures as screening the ventilators of septic tanks with gauze and the periodical disinfection of privies, while with regard to *A. aegypti* it could be exterminated by forbidding the growing of banana and taro, the leaves of which are its favourite breeding places. *Aedes variegatus* presents a more difficult problem, but the author is able to state that the measures adopted greatly reduced the numbers of the mosquito. Its breeding places are coco husks and shells, cecrop pods, rotting crinoids in trees, crab holes in sandy places on the shore, water butts, discarded vessels, and the like. Systematic work by trained health inspectors would soon reduce the number of mosquitos from these sources, but in the present state of knowledge extermination is impossible owing to the proximity of great forests with their innumerable little rot-holes which are the stronghold of the insect. The only measures, therefore, at present available are constant inspections and repeated cutting of bush, these are expensive and not generally efficient, and the conclusion is reached that the only prospect of efficient control of the insect lies in the still further study of it, in the hope of devising some plan which will give some measure of permanent reduction in its numbers. The problem is an important one, since it is estimated that 58.3 per cent of Simorians over fifteen years of age are infected and suffer from the associated diseases.

A considerable part of Dr. Burston's volume is devoted to a description of experiments performed on *Aedes variegatus* and *argenteus*. Thus experiments were carried out with a view to studying the factors which control egg-laying, the factors which cause the eggs to hatch, the mortality of the insect, the length of the larval and pupal stages, the relation to temperature and food supply, salinity, and the amount of light. Further experiments dealt with abnormal conditions such as starvation, poisoning, and putrid drying. The work concludes with an interesting general summary of the natural history of the insect, based on the author's own work and other published researches. A statistical account of malaria and filariasis is added by way of appendix, and two appendices on the hatching of *Aedes variegatus*, one by Dr. J. F. C. Huston and the other by Professor M. Greenwood and I. M. Newbold, are included in the volume.

The volume is beautifully got up and contains a large number of figures illustrating diagnostic points in the structure of the insects and photographic plates showing the special features of their breeding places.

#### FOLK-LORE AND MEDICINE

DR. DAN MCKENZIE, who has written pleasantly and effectively on various themes, professional and lay, has in *The Infancy of Medicine* discussed the questions in what manner and to what extent primitive thought has influenced the evolution of the science and art of medicine. The subtitle, "An Enquiry into the Influence of Folk-Lore upon the Evolution of Scientific Medicine," defines the scope of the essay, which won the prize in the history of medicine at the University of Glasgow in 1925, it is modestly dedicated as "a small tribute to the honour and glory" of the author's Alma Mater. The analysis and description of primitive psychology contained in these well-written chapters, which really constitute a

series of essays, may, it is suggested, among other uses provide the young practitioner with a key to "the more obscure workings of the partially educated lay mind." There can be no doubt that it is a store of material most useful to the increasing number of medical men interested in the history of their profession.

The first part, rather less than a quarter of the volume, deals with primitive medicine in a general manner in three chapters on the evolution of the medical man, primitive pathology, and primitive treatment. The savage medicine man, it is noted, was for centuries linked more or less closely with the priest. Later he attained an independent position, and in attractive account is given of Egyptian medicine. Among much information on primitive pathology it is suggested that the discovery of calculus in the body may have given rise to the idea of a "soul" or the mystical propulsion of a concrete substance into the victim's body, analogous to the entrance of a bullet. While demoniac possession ranked higher than magic as an etiological factor, the latter was regarded as more effective in primitive therapeutics.

The fourteen chapters of the second part deal with individual groups of methods of treatment, and trace the way in which the present position of medical thought has been evolved. Beginning with full descriptions of the evolution of animal and botanical remedies, astrology, the employment of stones, soul cures, healing wells, charms, numbers, the evil eye, and cures by saliva are reviewed in detail. Further chapters deal with midwifery, pregnancy, and menstruation, with surgery, major and minor, and with counter-irritation, and emmenagogue and other mutilations, thus bringing to a close a work which must have cost years of persevering research, much thought, utilization of experience, and hard writing, for it certainly makes easy reading, and compels admiration.

#### ANTE-NATAL AND POST-NATAL CHILD HYGIENE

DR. FELDMAN'S treatise on *The Principles of Ante-natal and Post-natal Child Hygiene* is intended to be a companion volume to his previous publication on *The Principles of Ante-natal and Post-natal Child Physiology*, which was noticed favourably in 1920. The new book is a worthy successor, and its comprehensive grasp of a wide subject, its well arranged mass of detailed information, and its full bibliography, conveniently grouped at the end of chapters, should ensure for it a welcome by all interested in infant and child welfare. The history and development of child hygiene through the ages is treated by the author in fifty pages crowded with graphic details, these are followed by a chapter on biometrics, in which the modern methods of statistical analysis are applied to some of the problems of child hygiene. The remainder of this introductory part of the book is devoted to a consideration of the causes of death and their prevention in the ante-natal, neonatal, and post-natal states, together with the question of maternal mortality. The second part of the book deals with ante-natal hygiene, and the third part with post-natal hygiene from birth to the onset of puberty. It is impossible to describe fully some 750 pages of carefully collected facts, reasoned conclusions, and practical suggestion. The chapter headings may serve, however, to indicate the ground that is covered. They include: general hygiene, breast and artificial feeding, the nutrition of infants and children, care of the teeth and the organs, prevention of infectious diseases, physical and mental growth, and the hygiene of adolescence. The other subjects are dealt with concisely but in detail, the attractive style of the writing preventing the weariness of reading that would otherwise be inevitable. The author has attempted, and has succeeded in, the difficult task of producing a book which will interest able pediatricians, lay workers at infant welfare centres, and all concerned with ante-natal care and welfare, and all concerned with the well-being of children. The general practitioner will find it answers to the innumerable questions of

*The Principles of Ante-natal and Post-natal Child Hygiene.* By FELDMAN, M.D. B.S. M.R.C.P. (Lond.). F.R.S. (Ed.). London: Daniel and Co., Ltd. 1927. (Demy 8vo pp. xxiv + 753 net.)

parents. The book is provided with an abundance of illustrations and there are two good indexes, one dealing with subjects and the other with the names of authorities on child hygiene.

### VOCATIONAL GUIDANCE FOR THE TUBERCULOUS

Messrs W I HAMILTON and T B KIDNER have held various posts in America in what they call personnel and rehabilitation work. From their experience in this they have produced a chatty little book on *guiding the Tuberculous about Employment*, into which they have managed to compress a large amount of information, together with a useful bibliography of the subject. The authors consider that the keynote of work in rehabilitating the tuberculous person is "individualization," and they describe the investigations necessary for what they term "vocational advisement."

They call attention to the evils of encouraging amongst the disabled the "hero of the new job," and they lay down the principle that efforts should be made to return a man to his old, or an allied, job. They believe that village settlements are chiefly valuable in giving opportunity for prolonged convalescence, and that, even if a few permanent settlements are established by philanthropic individuals, very few dwellers in such settlements will become permanent settlers, or "colonists." It is an alternative to village settlements in solving the problem of the employment of ex-patients, the special workshops of the Aero Manufacturing Company of New York are described. This enterprise was started some years ago by a leading Hebrew hospital and social welfare organizations. It provides part-time work, paid on a piece-work basis, under medical supervision, with periodic re-examinations of the worker, so that his work and rest are regulated in accordance with his physical conditions. No patient is regarded as cured until he has had at least two years' continuous good health after sanatorium treatment. Apparently the experiment has been a great success, and the industry is now housed in a fine modern factory building.

Messrs Hamilton and Kidner's book should be useful to workers in vocational guidance.

### WORLD HYGIENE

Is that complex of nations which go to make up the manifold world of to-day national health, like national prosperity, is not solely a national problem. It reverberates upon our countries both neighbouring and remote. They must and do as prudence suggests put up their barriers against "infection" from beyond their frontiers as against "the hand of war," but with the broadening altruism of our age inter-relationships are being established and the health of nations too weak to help themselves has recently become the voluntary care of the strong. An interesting commentary on the system of procedure which gives effect to these good enterprises is contained in Dr C W HERR's *International Hygiene*, which deals among other topics with the international sanitary conventions, immigration and emigration, venereal disease, noxious drugs, the traffic in women and children and industrial hygiene. The work is relieved by vivid passages, as in the account of the drastic means adopted by the Chinese Republic in 1912 to suppress opium smoking. The President made the taking of opium an offence punishable by death. Thousands were put against a wall and shot by firing parties and men were beaten senseless in the midst of their ruined fields. The export of Indian opium to China was abolished. And the result was that opium was grown in Korea, the Japanese drove a roaring trade, and the cultivation of opium in China itself increased by leaps and bounds. There is a graphic note on the clearing of the island of Principe of sleeping sickness by measures which included the perambulation of the jungle by negroes wearing a back piece of bird lined cloth as a net for paper.

*International Hygiene* by C W Herr. Ed. by W I Hamilton and T B Kidner. London: Baillière Tindall and Cox, Baltimore, The Williams and Wilkins Co. 1937 (Pp. 320, 15s. 6d. net).

### NOTES ON BOOKS

In reviewing the first volume of the third edition of Baly's *Spectroscopy* about two years ago we said that the subject was growing rapidly, and was destined to attract an increasing number of experimental workers, so that it was not surprising that the bulk of the treatise had increased. A second and third volume have now appeared, and complete the work. The second describes the application of interference methods and treats of methods of illumination, the nature of spectra, fluorescence and phosphorescence and the photography of the spectrum. In each of these sections a vast amount of research has been carried out by many workers and the products of their labour stood in need of being collated, connected and compared. Professor Baly, both by his extensive knowledge of the work done and by his own share in it, is well qualified to perform this duty, and he has spared no effort to make his treatment comprehensive. He is therefore to be congratulated that having such a large volume of matter to deal with he has yet succeeded in giving to every subordinate incident a description which will be most helpful to anyone engaged in the study. Not least important is the attention he has devoted to historical sequence in the various developments of discovery. In the third volume theoretical considerations of the electronic structure of the atom are discussed and the development of modern theory described. The plain recital of this development in the spectral series and of the Zeeman effect would alone have made a considerable treatise, but the author has been indefatigable in writing a story of forty years' progress dealing minutely with each advance, great and small, mainly in their order of sequence. Chapters on the Stark effect and emission band spectra prepared with the same thoroughness complete the volume. The book appears destined to be the leading authority on the subject.

The *Abstracts of Dissertations Approved for the Ph.D. M.Sc. and M.A. Degrees in the University of Cambridge for the Academic Year 1936-1937* are forty-four in number and naturally deal with a wide range of subjects in the Faculties of Agriculture, Biology, Classics, English, History, Mathematics, Medicine, Physics and Chemistry. The Faculty of Biology is divided into two under the heading of Biology. There are dissertations on botanical and geological problems, and under Biology B on experimental psychology and biochemistry. Dr C S Hicks's dissertation for the Ph.D. degree dealt with the chemical and physiological relationships of thyroxine and there is doubt on the formula originally suggested by Kendall, that of Mrs D M Needham on the pH and pH of the cell in *eric* was based on the microchemical injection of pH indicators into the interior of *Amoeba proteus* marine cells and a few facultative anaerobes, and that of Dr Harold Taylor on the hydrogen ion concentration of the blood cells. From the Faculty of Medicine there are two dissertations. Dr Stanley Griffith gives the results of his prolonged investigations into the etiology of human tuberculosis in Great Britain and Dr J P Hoet discusses three different points—the rate of sugar disappearing under the action of insulin, the onset of rigor mortis and the action of drugs on the spleen. The abstracts are of course succinct but the dissertations are deposited in the University Library where they can be consulted.

The third volume of the *Annals of the Priestley Thorpe Research Laboratory* contains a historical survey of researches on the streptococci generally. It is stated that the next issue which it is proposed to publish in 1937 will deal with the pathogenic forms. The present volume indicates how differentiation of the many varieties of streptococci may be facilitated. It includes a large number of photographs and also coloured plates illustrating the use of Dr Warren Crowe's differentiating medium. The general arrangement, the full bibliography, adequate indexes of authors and subject, and the compilation of an immense amount of information should render this volume of considerable assistance to working bacteriologists.

*Medicus* is the French equivalent of the *Medical Directory* but in some directions its range of information is even wider. Thus it describes the regulations and courses of the faculties of medicine and pharmacy of the military and colonial

### CAPTAIN COOK'S HYGIENE

CAPTAIN T. S. ANGUS, FRGS, FRAS,  
MASTER MARINER

UP to the time of Captain James Cook's first voyage round the world in H.M. bark *Endeavour* scurvy was the scourge of the sea service on long voyages. It was left to this son of a farm labourer, born in 1728 in a small two-roomed cottage (a "clay biggen") at Minton in Yorkshire, to prove during his three long voyages of exploration how this pest could be completely vanquished. James Cook first went to sea as a boy in a North Country collier vessel, and after some twelve years in this rough trade had reached the post of first mate. Scurvy would certainly be unknown on these colliers as the voyages between ports only lasted a few days, but after he had volunteered into the Royal Navy as an able seaman (he was promoted to master's mate five weeks from first entering) he soon became acquainted with scurvy and other sicknesses to which seamen of the time were liable. The *Eagle* on which he first served, returned to port with 150 men on the sick list out of a crew of 400, this was after only a three or four months' cruise in the Channel and Bay of Biscay. The chief cause of this high rate of sickness seems to have been that the men were insufficiently clothed, having been hurriedly impressed owing to the great shortage of seamen at the time. After two years Cook was promoted master, and served in that capacity on the North American station, where he had abundant experience of scurvy. How he distinguished himself at the taking of Quebec by Wolfe, and surveyed the coasts of Newfoundland which brought his character and talents prominently before the Admiralty and Royal Society does not come within the scope of this sketch. Suffice it to say that he was afterwards selected to command the *Endeavour* which was sent to Tahiti in the South Sea Islands to observe the transit of Venus in 1769. On passing Cape Horn into the Pacific on the way to Tahiti, his surgeon was able to report that the crew were as free from scurvy as on the day they left Plymouth five months previously. After leaving Tahiti, where the transit of Venus was successfully observed, he proceeded to New Zealand a small part of which had been discovered by the great Dutch navigator Tasman. Cook spent six months in sailing round the islands and charting the coasts and harbours he saw with wonderful accuracy considering the means at his disposal, and then sailed for the east coast of Australia which he explored and charted unfortunately while thus engaged his ship ran on a coral reef off the Queensland coast and was nearly lost with great difficulty he succeeded in getting her into a small river where he beached her and effected temporary repairs. The prosperous Cooktown now stands at the place where the ship was laid ashore for repairs. Eventually he was able to put to sea but with a very leaky ship and sailed up the coast through most dangerous navigation. The whole of this coast had never been visited by a European before. Passing through Torres Straits he at length reached Batavia and on the day of his arrival he sent a short dispatch to the Admiralty by a Dutch ship in which appears: "I have the satisfaction to be able to say that I have not lost one man by sickness (scurvy) during the whole voyage. This was indeed an achievement and had it not been for the unavoidable delay at Batavia needed to repair the ship—for the damage she had received on the reef was found to be very much greater than Cook knew—there is no doubt he would have been able to say the same when he arrived in England. It happened that it was a very sickly season at Batavia, and his crew and officers rapidly fell ill with fever and dysentery which continued for some weeks after he left, and before he arrived at the

Cape of Good Hope he had lost thirty-four persons out of his complement of ninety-four.

The scorbutics cruised in the ship, with some others, were chiefly

Malt to be made into a wort aurkrou orange and lemon juice portable soup sugar and vegetables at all times when they could be got. These were of such infinite service to the people in preserving them from scorbutic taint that the use of the malt was (with respect to necessity) almost entirely precluded. At Tierra del Fuego wild celery was collected and every morning breakfast was made of this herb with ground wheat and portable soup. No opportunity was ever lost of getting wild celery or any other wild herb that was to be found.

In a paper read before the Royal Society, Cook himself says,

But the introduction of the most salutary articles either as provisions or medicines will generally prove unsuccessful unless supported by certain regulations. On this principle many years experience enabled me to lay a plan whereby all was governed. The crew were at three watches except on some extraordinary occasions.

In the ordinary way the thirty able seamen he had in the *Endeavour* would have been divided into two watches for the ordinary work where fifteen men would be always on deck attending to the sailing of the ship and the other below off duty night and day every four hours alternately, this is known as "watch and watch" or "four hours on and four hours off," as the men themselves call it. On this plan the seamen would never get more than four hours sleep at a time. With three watches the men would be divided into groups or watches of ten men and that number on deck would be quite sufficient to sail a small ship like the *Endeavour*. In ordinary weather conditions every seaman would have eight consecutive hours off duty twice in twenty-four hours with two four-hour watches on deck intervening. Cook goes on to say,

By this means they were not so much exposed to the weather as if they would have been at watch and watch, and generally had dry clothes to lift them selves into when the happened to get wet. Proper methods were used to keep their person, hammocks, clothes, etc. constantly clean and dry. Equal care was taken to keep the ship clean and dry between decks once or twice a week she was cured with fire. When this could not be done she was mowed with gunpowder mixed with vinegar or water. I have frequently used a fire in an iron pot at the bottom of the well (where the lower end of the hys pumps go for pumping out bilge water) which was of great use in purifying the air in the lower parts of the ship. To this cleanliness as well in the ship as among the people too great attention cannot be paid. The least neglect occasions a putrid and disagreeable smell below which nothing but fires will remove.

Proper attention was paid to the ship's coppers so that they were kept constantly clean. The fat boiled out of the salt beef I never suffered to be given to the people being of opinion that it promotes scurvy. I was careful to take in water whenever it could be got even though we did not want it but always had plenty for every purpose.

Cook had great difficulty in getting his seamen to eat the nauseous strange messes he had had cooked for them—portable soup boiled with wheat wild celery etc.—but he had the same at his own table in the wardroom with his officers, and insisted that they should be eaten. When the men began to realize that the captain and his officers ate them they took to them and soon got used to them. It is recorded in the journal of his first voyage that two of the men refused to eat the fresh beef provided for them at Madena, for which he punished them with twelve lashes each.

So far I have only referred to Cook's first voyage in the *Endeavour* a small vessel of not more than 366 tons burthen 97 feet long by 29 feet broad and 11 feet deep. The height between decks where the crew berthed was only about 5 feet so that with all her people on board it was pretty close stowage showing that only by unremitting care and attention on the part of the captain could her crew be kept in good health. On Cook's second voyage he had two ships also like the *Endeavour*, built at Whitby for the coal trade and likewise selected on Cook's strong recommendation as being the most suitable type of vessel that could be got for the purpose. The select crew was most

amply justified. This second voyage lasted for three years and eighteen days, and in that time, on his own ship, the *Resolution*, he did not lose one man by scurvy or any other sickness. His consort, the *Adventure*, on the other hand, lost several men from scurvy, the reason for this was undoubtedly that Captain Cook was not on board that ship.

After arriving home from that voyage he was unanimously elected a Fellow of the Royal Society, and immediately after starting on his third and last voyage he was awarded the Copley medal.

Again he had two ships, he was unfortunately killed in an affray with the natives at Havan, but Cook's work was most thoroughly accomplished, and both his ships arrived home after an absence of four years and two months without a single case of scurvy occurring in either ship, showing that after his lamented death the officers who succeeded him thoroughly carried out his system of curing for the health of the crews.

In conclusion it may be of interest to add that Captain Cook's name was often quoted at sea in my young days in connexion with cleanliness and using the fat boiled from the salt beef, which sailors were fond of adding to their extemporized messes. Also, if a sailor grumbled about being set to a job which he thought was not of much use, he would be told it was to "keep the scurvy out of his bones." It is well known that Cook used to keep his people well at work, always finding something useful for them to do, even in the most relaxed times.

### CANCER RESEARCH IN FRANCE

The study of cancer has led in France to the establishment of a system of regional anti-cancer centres. The idea was put forward by the late Professor Bergonié of Bordeaux, and taken up by his friend M. Paul Strauss, who had been interested for many years in public health questions and recently was Minister of Hygiene. In 1922 M. Strauss formed a "Commission du Cancer," to inquire into the steps which should be taken to develop the idea, with Dr. Rouse, director of the Institut Pasteur, as president. The committee advised that centres should only be established in places where a faculty of medicine or a *grande école* was already in existence, that they should be administered by the Minister of Hygiene, and that the objects of the centres should be treatment, teaching, and research.

As long ago as 1914 the Institut Pasteur had formulated plans for building in Paris a clinic and laboratories for an institution to be known as the Fondation Curie. The work was suspended during the war, but in 1919 it was begun again, and since that date the Fondation Curie has worked under the control of Professor Regaud. When Professor Bergonié's idea of anti-cancer centres materialized in 1923 Professor Regaud looked on it with sympathy, and in course of time the Fondation Curie and the various centres became affiliated. The present position is that the Fondation Curie remains entirely free from all Government control, and carries on its work in its own way, but it is looked upon as an inter-regional centre and works in close co-operation with the directors of the regional centres.

In forming regional centres existing departments of hospitals have been converted in many cases to meet the new requirements. In other centres entirely new buildings have been erected. There are now seven centres established in hospitals in Paris and its suburbs in the provinces there are eleven dispersed amongst the larger towns. Apparently it is not considered necessary that any more centres should be established. At present the centres display varying degrees of efficiency, since some have been at work for nearly three years, while others are still in the making. But the attainment of a high standard of co-ordination is furthered by periodic meetings of the directors for the discussion of new ideas and methods in the treatment of cancer. The chief methods employed at the centres are surgical and radiological.

We are indebted to Dr. Malcolm Donaldson and Professor Sidney Russ for a report on the work done at some of

these regional centres. The highest state of efficiency in organization and technique was, of course, found in the Fondation Curie, where several grams of radium are available for therapeutics and research. Remarkable results have been obtained in this institution in the treatment of carcinoma of the tongue and of the cervix uteri. In the former disease, according to Professor Regaud, nearly one-fourth of the number of out-patients have been thoroughly cured, while in nearly another fourth the lingual localization has disappeared. In cancer of the cervix a number of quite operable patients were living five years after treatment, many with no signs of recurrence. A curious occurrence amongst the cases treated in 1919 was that, while 6 out of 64 advanced inoperable patients, and 6 out of 18 borderline patients, were still living after five years, none of the 5 operable patients treated survived for that length of time. The improvement in technique at the institution is shown by the fact that, while the mortality at the end of one year was 65.5 per cent in 1919, in 1924 it had dropped to 28.7 per cent.

The observers visited also the centres at Strasbourg, Lyons, Marseilles, Montpellier, Toulouse, and Bordeaux. While all these centres were displaying activity, in most cases they had been developed too recently to enable their records of treatment to be of any value. Research, however, was being pursued in various directions. All the centres visited possessed some radium, and had effective x-ray installations. At Lyons, Marseilles, and Montpellier the director of the centre was a surgeon, at Strasbourg and Toulouse a radiologist, and at Bordeaux a clinical pathologist. The staffs attached to the centres varied in number and nature. Thus there were, in addition to the director, two medical men and six lay assistants in Strasbourg, in Lyons seven other medical men and nine unqualified assistants, in Marseilles one other surgeon, two pathologists, and two qualified radiologists. In Montpellier, where the centre at the Hôpital St-Jacques is linked up to the department of pathology at the Faculté de Médecine, there were five medical men in addition to the director, including three professors at the University. The Toulouse staff consists of six consulting surgeons, two medical assistants, one radiologist in addition to the director, a clinical pathologist, and a biochemist. At Bordeaux the director is assisted by surgeons, one radiologist, two assistant medical officers, one intern and three externs, and three pathologists. So far as radium treatment is concerned the researches at the Fondation Curie have been so systematic that the methods in use at that institution are followed largely at the other centres.

Financial support for the expenses of establishing and maintaining centres appears to be obtained from a variety of sources. Not only do voluntary subscriptions invited, and grants received from the municipality and the French Government, recourse is also had to the pari-mutuel. The Government grant does not seem, as a rule, to be very generous. The personnel of the centres sometimes consists of full-time salaried officers, in other cases it is honorary.

It is evident that in France a national effort of some magnitude is being made in the attempt to conquer cancer. The co-ordination of eighteen regional centres by means of the inter-regional centre, the Fondation Curie, must make for efficiency, and the periodic meetings of directors all engaged in the pursuit of improvement in teaching, treatment, and research should be stimulative of ideas. Dr. Donaldson and Professor Russ think that much may be learnt by other countries from the efforts that are being made in France to-day. They have not come back from their tour prepared to answer the question whether more cancer patients are being treated by better methods than formerly. They do not know whether more interest in the study of cancer has been aroused, or whether there is more widespread knowledge of the disease among the medical men of the country. They are, however, convinced that in France radiotherapy in connexion with cancer rests on a firmly established basis of clinical observation combined with laboratory researches of a fundamental character, and that the methods adopted are worthy of study by other workers in the field.

## THE PROTECTION OF MOTHERHOOD

As noted in our last issue (p. 1198) a report by Dame Janet Campbell, entitled *The Protection of Motherhood*,<sup>1</sup> has just appeared from the Ministry of Health in continuation of her previous report on Maternal Mortality.<sup>2</sup> It analyses the figures and summarizes the progress of the four years between the two publications, and being more constructive in spirit and less controversial in tone should be the more helpful in pointing the way to a real advance. One of her conclusions is worth quoting as it would appear to be her justification of or apology for the effect of the maternal mortality report upon the practitioners of the country. The reason for dwelling upon the tragedy of an unnecessarily high maternal mortality rate is not for the sake of criticism or censure, but because until it is realized that much of the poignant sorrow and suffering caused by misadventure at the time of childbirth is not inevitable and can be lessened we shall be slow to find the time, money, effort and goodwill needed to persuade all concerned to combine to overcome the practical difficulties of this problem. A convinced public opinion has magnificent driving force and without it endeavour is apt to be half-hearted and to faint by the wayside.

The text on which this report is based may be found in its concluding paragraph—It is only upon a foundation of healthy, happy and contented motherhood that we can hope to build up a Nation sound in mind and body—and its constructive character in this direction is indicated by the prominent place given to schemes for improving the maternity service and providing means by which supervision and assistance may be secured for every child-bearing woman during the ante-natal, natal and post-natal stages. The recommendation of the Royal Commission on National Health Insurance that the scope of the maternity benefit should be extended is taken as the foundation on which a maternity service can best be built. Besides the cash payment on confinement medical and nursing services should be provided and linked with the maternity services set up by the local health authority or by voluntary effort. As the personnel of these services would be largely family practitioners and midwives it will be of interest to indicate the nature of the suggestions made in the report under consideration.

Doctors and midwives must be regarded not as rivals but as members of a team each with their own part to play. The general supervision of the women during child-bearing will fall to the medical member who will be responsible for the ante-natal examina-

tion of all his patients and will remain directly under his care cases of complicated pregnancy or labour, or those in which difficulty in labour may be anticipated. The proposal of the British Medical Association and other bodies that provision should be made for attendance of a doctor and midwife at every confinement would usually mean that the normal labours would be conducted by the midwife and medical aid only summoned for delay or complication. This arrangement is regarded with favour in the report, because it relieves the medical side of much unnecessary tax and yet allows experience of normal labour to the young practitioner so long as he wishes to avail himself of it. Besides managing many normal labours the midwife would perform all the maternity nursing. Supplementary services—such as hospital and clinic facilities, consultations with specialists, and skilled nursing—would be provided where necessary by the local authority in order that the standard of actual obstetric practice may be raised. With the object of attracting well educated and better trained women to practise as midwives an increased appointment of municipal midwives is advocated. They should be allowed to do private practice and work in conjunction with private practitioners—but it is suggested that all fees earned in this way should be returned to the local authority. The disappearance of the independent midwife would be regretted and the pious hope is expressed that some method may be found of bringing the competent private midwife into close association with the local authority and enabling her to maintain her position in the maternity service.

A feature of this as of the previous report is the space devoted to puerperal infections as the largest single factor in the production of maternal mortality and disability. Though some reduction in the septicaemia mortality rate occurred in the early years of the century the last few years have shown a tendency in the opposite direction. A number of cases or outbreaks of infection in maternity institutions are analysed with the object of illustrating the dangers or spread where puerperal women are congregated and the importance of not neglecting early warnings or a focus of infection in an institution. An appendix on the bacteriology of puerperal pyrexia by Dr Eastwood the senior bacteriologist to the Ministry of Health is included and contains a summary of the application of bacteriological data to clinical practice. Dr Eastwood is cautious and non-committal and sets out clearly the reasons for the slow advance of bacteriology in close relation to clinical medicine. On the scientific ground that the data are as yet insufficient he refuses to express any opinion as to the relative importance of exogenous and autogenous infection. The point that stands out most clearly is the need for further laboratory research in close contact with clinical cases of puerperal sepsis.

This report by Dame Janet Campbell should be carefully studied by the medical profession as a whole, for it indicates the growing tendency to bring private practice alike of doctor and midwife under the control of the local or central health bureaucracy. To the general practitioner it is particularly of interest in that it endeavours to answer two questions that greatly concern him in his maternity work—namely, Is he getting the best possible equipment for this anxious and exacting work? and Can anything be done to relieve him of certain responsibilities and to enable him to concentrate his effort upon the essentially medical aspects of midwifery practice?

## SYMBIOTIC FERMENTATION

MANI years ago it was shown by Marshall Ward that two micro organisms living in close association may initiate changes which neither of them can produce when acting alone. This he observed in the case of the "ginger beer plant"—the changes brought about by the conjoint action of a yeast and a bacterium in a saccharine fluid resulted in a preparation resembling ginger-beer, a result not obtained with either of the organisms acting alone. These observations of Marshall Ward have long been quoted as providing the classical example of microbial symbiosis. Nenehi soon afterwards recorded the formation of normal butyl alcohol from glucose solutions by the combined actions of *B. parafactor* and *B. chauraci*, neither of these bacteria in pure culture being able to produce this substance.

Interesting observations on the results of this close association or symbiosis of bacteria have been noted in the formation of various organic acids. Thus Sherman and Shaw reported that the yield of propionic acid by *B. acidipropionici* in lactose media was increased six or sevenfold by the addition of *Streptococcus lactis* or *Lactobacillus casei* to the cultures. Again, during the great war acetone and butyl alcohol were produced on the large scale by the fermentation of cereals and other carbohydrates with *B. granulobacter pectinovorum*. It was noticed that a diminution or even complete absence of the formation of acetone with a rise in the production of lactic acid occurred, and this was found to be due to contamination of the cultures of *B. granulobacter pectinovorum* with Thaysen's *Bacterium volutans*. This result appeared to be due to an altered metabolism in the acetone producing organism. A somewhat similar inhibitory action in the fermentation of lactose by *B. coli* was observed by Theobald Smith and D. E. Smith to be produced by the addition of paratyphoid bacilli, while a marked difference between the effects of hog cholera strains and those of paratyphoid bacilli was noted. All degrees of inhibition were observed, depending on the age of the cultures, living and functionally active bacteria, or those only recently killed, were necessary. It was suggested that the inhibitory factor was some metabolic product of the paratyphoid bacilli, probably of the nature of an enzyme.

Several studies of the biochemical characters of certain bacteria when living in association or antiferrially mixed and when living separately have recently been recorded by Castellani. This observer had noticed many years ago that ordinary baker's yeast, whether in Ceylon or in England, consisted, as a rule, of two or more organisms (saccharomyces and bacilli) living in symbiosis, and that in some cases baker's yeast gas fermented a larger number of sugars than did any one of the isolated organisms. In recent years he has extended his investigations to include a study of the action of certain pathogenic germs in symbiosis with others. The same phenomenon has been observed in these cases also, and is described at length in his latest contribution to the subject, which appears in the *Journal of Tropical Medicine and Hygiene* for October 1st, 1927. These results have now been confirmed by Frillos, Peruzzi, Menon, and others. An example of what Castellani terms the "symbiotic fermentation phenomenon," and which was termed "Castellani's fermentation phenomenon" by Frillos in the same journal for December 1st, 1925, is afforded by the results he records with *B. typhosus* and *B. morganii* acting singly and combined, on each

of the three carbohydrates maltose, mannitol, and sorbite. Acting on each of these three substances *B. typhosus* produces acid only, never gas, whilst *B. morganii* has no action on any of them, producing neither acid nor gas. Acting together, however, gas in each of these three carbohydrates. Castellani accordingly defines his "symbiotic fermentation phenomenon" as follows: "Two micro organisms, neither of which alone produces fermentation with gas in certain carbohydrates, may do so when living in symbiosis or when artificially mixed." He further applied this phenomenon to the differentiation of certain organisms, particularly to those comprised in the dysentery group, and in the identification of certain carbon compounds, although in the latter case he admits that the mycological method of Castellani and Taylor is undoubtedly much simpler.

The latest contribution to this subject, from the pen of Ishikawa, appears in the *Journal of Infectious Diseases* for September, 1927. He discusses gas production by bacterial symbiosis, with special reference to the influence of nitrogenous substances, and finds that the non proteolytic gas forming bacteria alone cannot produce noticeable amounts of gas from carbohydrates and salts of formic acid in media containing only complex nitrogenous substances, such as milk, ascitic fluid, casein, nutrose, and gelatin, but that gas is generated intensively by these bacteria in such media if they are grown in association with the proteolytic bacteria, and demonstrable amounts of gas are produced if simple forms of nitrogenous substances—the digestion products of proteins, peptones, amino acids, and ammonium salts—are added to such media. The formation of gas from carbohydrates by the associative cultures of two kinds of saccharolytic bacteria—an acid producing organism and a gas forming bacterium—does not take place markedly in ascitic fluid, casein, nutrose, and gelatin media, except under the following conditions when a proteolytic organism is cultivated in association with the two saccharolytic bacteria, or when simple nitrogenous substances—peptone, amino acids, and ammonium salts—are added to the media.

The part played by the proteolytic bacteria in the above mentioned cases appears to be that they provide the way for the fermentative activity of the saccharolytic bacteria by breaking down the proteins of the media into some simpler forms of nitrogenous substances, which apparently are essential to the formation of gas. It seems probable that such simple nitrogenous substances accelerate the activity of the production of the specific enzyme, formase, which is considered to be responsible for the production of the gas. The precise nature of this bacterial symbiosis has not yet been fully determined. The stage of growth and functional activity of the bacteria concerned, and the hydrogen ion concentration with its regulation by the bacterial products, all appear to play important parts in obtaining the various results. As already stated, all degrees of the phenomena can be obtained, depending as they do on the character of the bacteria used, their age, and the employment of culture media of different composition. Further analysis of the gases produced may help to throw some light on the mode of action. There appears, however, to be good ground for believing that the acid and gas producing factors are different in time and probably depend on different endo enzymes. The further intensive study of these interesting phenomena is clearly indicated, and they provide a

wide field for exploration by the biochemist and physicist, whose labours would probably add much to our present scanty knowledge of the intimate mechanism of the bacterium.

#### PHYSIOTHERAPY FOR INFANTILE PARALYSIS

IN the course of the fifth Congress of French-speaking Pediatricians, held at Innsbruck last autumn, two papers on the treatment of infantile paralysis were read. One by Dr. P. Duhem dealt with physiotherapy and the other by Dr. P. Nicod, with orthopaedic considerations. According to H. Lemaire, who contributes a report of the congress to a recent issue of *Le Nouveau Médical*, Duhem expressed the opinion that treatment by irradiation was of very little value, and given rise of the paralysed muscles often inadequate. Restoration of muscle function was better achieved by rhythmic galvanism obtained by introducing into the circuit a rectifier which interrupts the current at intervals or a second. This procedure was usually employed when the reaction of degeneration was not very pronounced, and might be used up to the point at which it lacked a maximal contraction. Baudet in 1914, had advocated three exposures to x-rays each month for a period of three months, the application being made at the level of the cervical or lumbar enlargement of the cord. Duhem suggested that irradiation acted here by destroying the inflammatory tissue and permitting recovery of the more resistant motor cells. He added that diathermy and local hot baths were also very effective in restoring the muscular response to stimulation by electric currents, but diathermy must be used with great caution since burns were easily caused. One electrode was large as possible should be placed over the lumbar or cervical dorsal region and the other on the affected limb. The temperature recommended for hydrotherapy was 100° to 112° F. Massage was only beneficial when the atrophied muscles had recovered functional power. Nicod, discussing orthopaedic treatment, insisted that immobilization of the paralysed muscles in the position of physiological relaxation was essential from the commencement; splints should be removed at regular intervals so as to allow massage and passive exercises and testing of the limb's voluntary motion. When regression of the paralysis had ceased operation might be required to correct deformity and permit fuller use of the limb. In Nicod's view the best surgical procedure is arthrodesis, with perhaps some tendon operation.

#### POPULARIZATION OF MEDICAL SCIENCE

THE Harvey Society of New York was founded with the object of diffusing scientific knowledge of pathology and the allied sciences through public lectures given by actual workers in the subjects presented. The lectures were to be subsequently collected and published in a book. The *Harvey Lectures* for 1925-26 include several of much interest, more especially one on the parathyroid glands by Professor J. B. Collip and another by Professor F. B. Wilson on capitalism and rationalism. The former is practically an essay on the whole subject of the parathyroids but contains more particularly an account of experiments showing the action of the hormone on dogs and the relation of the gland to calcium and phosphorus metabolism. Recent studies in parathyroidectomized rabbit indicate that the part played by phosphorus in this has not been sufficiently stressed. The inorganic phosphorus in these animals increases enormously after the

removal of the parathyroid glands, and tetany or a marked type quickly develops, followed shortly by death. Injections of parathyroid hormone or even of calcium chloride may be of no avail in these cases when once the tetany has become manifest. The blood calcium is found to be lowered as in the dog and cat. In both these animals ovoids go with the hormone is followed by urgent symptoms which are coincident with a falling calcium curve and a rising phosphorus curve, and it is probable that the symptoms are due more to the blood phosphorus change than to the high blood calcium which precedes the fall. The rise in blood phosphorus would therefore seem to be the natural direct signal of ovoids rather than the blood calcium value. Professor Wilson's paper deserves to be widely read. It deals with the limits of usefulness of the statistical method. He does not condemn the method (he is a professor of statistics) but he points out that mathematical conclusions may be weaker than the premises on which they are founded, because of the necessary assumptions which are so apt to creep in. Any method, by the very fact that it is a method may tempt persons to confide their fortunes to it, ending in their own destruction (a reflection suggested by the lecturer's proximity to Wall Street at the time). Moreover the imagined beauties of their own speculations may lead them too far afield and prevent their ever finding their way back to nature. As germane to this topic he looks with some misgiving on the great elaboration of experimental apparatus in the hands of the young investigator and suggests that such elaborate equipment may perhaps shield him from wholesome contact with the stubborn facts of nature. For the beginner he recommends less of the theoretical and quantitative and more of the concrete and qualitative. If I knew a young fellow who ought advice about love I should not send him to his room to study Balzac's *Physiologie du Mariage* or Bourget's more ponderous *Psychologie d'un amour malade* nor yet to a clinic to be 'psyched' à la Freud, I should tell him to go and see some girls.

#### PUERPERAL SEPSIS ITS DEFINITION AND TREATMENT

AMONG the papers read at the Royal Sanitary Institute's Congress at Hastings and published in its *Journal* for November was one by Dr. Remington Hobbs on one reason for the high mortality and morbidity from puerperal sepsis. We publish this week (p. 1223) a further communication by Dr. Hobbs describing a method of draining the septic uterus. He objects to the definition of puerperal sepsis which was enunciated by the Ministry of Health at the suggestion of the Royal Society of Medicine—namely, 'a febrile condition or the nature of wound infection arising after labour or abortion due to bacterial invasion from or absorption of products of bacterial action from some portion of the genital tract.' Dr. Hobbs told the Hastings congress that puerperal sepsis is not necessarily a febrile disease and that the rest of the definition loses sight of the inflammatory changes which result from retained placental tissue, blood clot and lack of necrotic drainage. It would appear in fact that Dr. Hobbs attributes puerperal sepsis to interference with the outflow or secretions from the tissues and cavities of the genital organ. He regards pain and tenderness as the cardinal symptom and sign of lack of free drainage from the uterus. He thinks also that much more attention should be paid to prolonged haemorrhage after labour or abortion. Holding these views Dr. Hobbs regards all such procedures as curettage and swabbing with strong styptics or antiseptics as unsafe, and the injection of drugs or vacuum as valueless unless accompanied by free drainage or the genital tract. Hence his adoption of the method of glycerine irrigation described in the article we publish.

## THE JAMES MACKENZIE INSTITUTE

THE continued progress of the James Mackenzie Institute for Clinical Research at St. Andrews is clearly indicated by the eighth annual report, which has just been issued. The Institute—which, it will be recalled, was established in October, 1919, for the purpose of studying disease with a view to its prevention—has been engaged since then in promoting active clinical research by general practitioners associated with specialists, and in the provision of courses of post-graduate instruction to facilitate and intensify such research. Financial assistance for specific investigations has been forthcoming from the Medical Research Council, which contributes also £500 towards the compilation of the Institute records. During the winter of 1926 a course of lectures, free to medical practitioners, was given by various experts on the blood pressure in health and disease. Many of the lectures were subsequently published *in extenso*. It was not found possible to combine these in one volume, but it is hoped that this will be done in the case of the lectures delivered in 1927, of which reports have appeared from time to time in our columns among proceedings of medical societies. Papers on various subjects were read by members of the clinical staff of the Institute during the spring, and a post-graduate course was held during the last fortnight in June, which was attended also by students. Three volumes of reports have already appeared, and the fourth is in preparation. Considerable interest has been taken also in an attempt to correlate the public health activities of the local authority with the work of general practitioners. Special study is being carried on at the child welfare centre with reference to the first two years of life, and valuable records are being obtained illustrating such subjects as the significance of albuminuria, ovaluria, and acetonaemia in childhood, the frequency and prognostic significance of recurrent ailments such as bronchial catarrh, and the effects of environment upon the health of growing children. Recent gifts to the Institute include a recording ophthalmoscope, and additions to the library have been received from the Mayo Clinic and the Rockefeller Institute.

## RELATION OF PHYSIQUE TO MENTAL ACTIVITY

A NEWSYPER, in summarizing the lecture delivered recently to the Royal Anthropological Institute by Dr. A. A. Mumford, medical officer of Manchester Grammar School, misquoted him as upholding the view that "the better the scholar the better the athlete," and thereby started a correspondence in its columns from headmasters and others who declined against this supposed contention by Dr. Mumford, and said that in their experience excellence in both aptitudes was rare. But the argument in Dr. Mumford's lecture, the full text of which we have had the opportunity of studying, is much too carefully balanced to be adequately summarized by saying that he claimed any close connexion between "brawn and brain"—"brawn" in this instance meaning good scholarship, and "brawn" the development of the larger muscles. His purpose was to appeal for a fuller study of the differences observed among growing boys, both in mental attainments and in power to excel in physical activities. A detailed inquiry which has been proceeding over a period of years at Manchester Grammar School has revealed a slight positive relation—not a close connexion—between the physical and the mental aptitudes. The physique both of the scholarly and of the athletic boy tends to be superior to that of the average boy, and also the better scholars tend to have a better physique than the scholars less distinguished. In both cases the superiority appears to lie, not in muscular development, weight, and so forth, but in better breathing capacity and the improved body-build which results. These

conditions of function and structure enable the boy to endure the stresses involved in hard mental as well as hard physical activity. Dr. Mumford gave an interesting account of the annual body measurements which have been taken at Manchester Grammar School for over forty years, but especially since 1921, when a new system of grading was established. He was led to consider from a new point of view the common division of bodily exercises into those of strength, endurance, agility, and speed—namely, that of the different forms of body-build which are required for various excellences, and all of which may be comprehended in the term "physical fitness." He sees a danger if this term is taken indiscriminately, as a general certificate of security against disease or a guarantee of health. Physical fitness may be of more than one kind. The Medical Research Council did not succeed in its effort to apply to all forms of physical activity the Air Force physical efficiency tests, and Dr. Mumford, while he has found these same tests of great value when considering various forms of physical activity among schoolboys, has not expected to find any single test or group of tests to apply to all such forms. The school medical officer, he thinks, should appreciate how wide are the differences in the desired physical equipment for different individuals, having regard to their present school life and their anticipated career. He should not only make a routine physical examination by measurements and tests, but should compare the results of such examination with the boys' mental progress as reported by the masters. Class work in school calls for the activity of the same bodily organs and to some extent the same tissues as do physical exercises, though, of course, in a different way and to a different degree. Although undue absorption in either mental or physical activity involves damage to the powers thus over-stimulated and danger from under-development of the powers neglected, yet the proper exercise of physical powers is not only quite compatible with, but probably very beneficial to, the cultivation of mental powers. Dr. Mumford proceeded to give the results of an inquiry extending over twenty years upon a number of boys who gained entrance scholarships at Oxford or Cambridge, for the most part in open competition. The results again went to show that there was a general tendency for those boys who were accelerated in school progress to show acceleration also in physical robustness, particularly in the rate at which they required fuller respiratory power. These scholarship-winning boys tended to display an accelerated physical growth compared with the average boy. That they also possessed a slightly better physical frame was shown by the fact that the acceleration in the growth of chest girth—and therefore in breathing capacity—was rather ahead of the acceleration in respect to height and weight. This greater relative acceleration of chest girth also was most pronounced among the 102 boys of the group who obtained first class honours in one or both parts of the subsequent university examinations, as distinct from the 113 whose honours were of the second or third class, and Dr. Mumford thought this indicated that these boys were capable of maintaining a higher level of working capacity with less strain than others as a result of the combination of higher mental ability with superior physique. An attempt was also made to find out whether this total of 215 scholarship-winning boys, besides displaying energy which could be directed towards successful study, also possessed in any marked degree the energy which could be utilized in physical activity—that is, whether, taking the group as a whole, they showed special excellence in games and sports. The records were examined for records of colours for prowess in games or success in athletic contests, and it was found that out of 700 prizes competed for by 7,000 boys, 73 had been taken by members of this group of 215 boys who also possessed special mental ability. Here

in the greater the degree of mental excellence as judged by the honours obtained at university examinations the greater the degree of physical excellence as judged by the records. Thus one boy in ten in the first-class group, one boy in five in the second-class, and one boy in nine in the third-class were awarded colours. Moreover, in the first-class group nine of the boys showed special prowess in more than one form of physical activity, while in the second-class and third-class groups only two of the boys showed a similar distinction. In conclusion, Dr. Munford again pointed out that these investigations revealed tendencies only but they went to support the results or other observations in suggesting a certain relation between activity of the body and activity of the mind and in making it plain that the growth of the human frame should be viewed as unity, and not as growth of mind or body separately.

#### NEW YORK MENTAL HOSPITALS

With a prospect of amending lunacy legislation in this country, there is some interest in noting the progress of a similar administration in other countries. In the State of New York the mental hospitals are managed by the State Hospital Commission. The commissioners are three laymen and one doctor, and their last annual report informs us that, by a law passed in 1906 this work, together with the control of some other hospitals and supervision of mental defectives, is to be placed under the control of a Department of Mental Hygiene, with a single head, the Commissioner of Mental Hygiene, who is appointed by the governor of the State and retires with the governor. The department will have three divisions—of mental disease, of mental deficiency and epilepsy, and of prevention, each with its assistant commissioner. The old commission controlled some 45,000 beds and treated 56,751 patients in the last year, at a cost of four million pounds sterling. One-tenth of the total number were paying patients; the rest were paid for by the State. During the year 4,526 were discharged—1,771 as recovered, 242 as much improved, 1,017 as improved, 718 as unimproved, and 78 as not improve. The recovery rate on first admissions was 24.3 per cent, and on the total number of persons under treatment 3.3 per cent, 1,465 patients were transferred elsewhere. There is a medical examiner's office and the chief duty of this officer appears to be to send back to their home country aliens who are in need, and to transfer others to States or the Union whence they come. His work is described as efficient: last year 458 aliens were got rid of, and 758 non-residents were sent to their homes outside the State of New York. Admission appears to be by several methods. Voluntary admissions numbered 502 of these 221 were readmissions, 77 of the cases were later committed. One hundred were admitted on written petition and physician's certificate. Twenty physician's certificate cases were committed. Fifty-one mental cases were conducted by the several State hospitals, with an aggregate of 17,000 visits. It was hoped to have extended the clinic work to include school children with disorders or behaviour, but full co-operation or the educational authorities could not be secured. The medical inspectors made fifty-eight visits to the hospitals, and saw some 8,000 patients. All were recorded the privileges or the insanity law and given an opportunity to express themselves and their reasons for being there. Any requesting it were given a private interview. Thirty-four patients made complaint of ill treatment, but full investigation did not elicit anything to substantiate the complaints made. Twenty-six committed patients protested their confinement and detention, but in practically all of these a short interview and examination or the case history showed clearly the need of State hospital care. Visits are also

made to hospitals for criminal cases, to private licensed institutions, and to non-licensed institutions. The Commission maintains a school for mental nurses, and in this connection note is made of the lamentable decline in the number of pupil nurses, a lack which necessitates the substitution of trained attendants for nurses in the hospital ward.

#### HISTORY OF THE CLINICAL THERMOMETER

In *Medical Life*, described as the merger of the medical journal "one of which was the *Medical Oup* and another the *Medico Historical Bulletin*, in whose footsteps—possibly a better path—it appears to follow as regards its subject-matter, Mr. C. J. S. Thompson traces the history and development of the clinical thermometer. In 1623 Simon Stevin constructed one and advocated its use in the diagnosis of disease correlating variations in body temperature and weight, and this was much in advance of his time as seen of metabolism. M. du Val of Paris invented a clinical thermometer which was first shown in England at a meeting of the Oxford Philosophical Society on May 13th 1654. It was three inches in length and three or four lines in diameter, the central tube for the mercury being half a line in diameter; it was used in several Boerhaave's pupil van Swieten used Fahrenheit's mercurial thermometers for registering the mouth and axillary temperatures, De Haen made further observations, such as morning and evening fluctuations and the high level during a rigor. Fordyce Blagden, Bauk, and Solander experimented on themselves in heated chamber, and in 1780 Lavoisier and Laplace, working on thermometry, showed the dependence of animal heat on the combination of oxygen with hydrogen and carbon. John Spangin, physician to the Foundling Hospital, Haisseau Orator, and a follower of Swedenborg's philosophy, published in 1852 an account of a clinical thermometer, John Day in 1863 brought out his observations made in many parts of the world and in 1863 C. A. Wunderlich's essay based on observations of twenty years (translated in the New Sydenham Library in 1871) gave a real stimulus to clinical thermometry, though Aitken had used thermometers in English hospitals in 1855 and Sidney Ringer in 1865 had published a work on *The Temperature of the Body as a Means of Diagnosis of Typhoid, Measles, and Tuberculosis*. As is (or should be) well known, the late Sir Clifford Allbutt devised the present form of clinical thermometer first fitting it, when six inches long, into a stethoscope, and finally about 1867, reducing it to twice inches in length.

#### ROYAL SOCIETY OF MEDICINE

At the reception to be held by the Royal Society of Medicine on the evening of Monday January 16th, Dr. Jane Walker will give an address entitled "Saints' Medicine and Surgery." The Wellcome Historical Medical Museum is providing a series of interesting exhibits, including statues of saints to whose intercessory cures or various ills have been attributed and also ex voto offerings to the saints, and to Grecian and Egyptian deities created with similar powers. Dr. Jane Walker has secured reproductions of many old paintings illustrating her subject and in her search for material has had access to the catalogued collection of pictures in the possession of Sir Robert Witt (Trustee of the National and Tate Galleries). On this occasion guests will be received by the President from 8.30 to 9 p.m. as usual, but the address will be given at 9.15 instead of 9.30 as hitherto. Admission to the social evening is open to Fellows or the Society and their friends, but tickets are necessary for visitors not accompanied by a fellow.

## Union of South Africa.

[FROM OUR CORRESPONDENT IN CAPE TOWN.]

### NEW HOSPITAL REGULATION CAPE PROVINCE

A REGULATION (framed under Section 72 of the Cape Hospitals and Charitable Institutions Ordinance of 1912) governing the attendance on patients in hospitals by medical practitioners not on the staff was published recently in the *Provincial Gazette*. The regulation reads:

(1) Subject to the provisions of subparagraph (2) of this regulation

(a) Any registered medical practitioner who is not on the staff of the hospital desiring to attend patients paying three shillings and sixpence per diem or over towards their maintenance shall apply to the board for permission so to do, and no such practitioner shall have access to the hospital for the purpose of so attending patients until he has received the approval of the board thereto in writing.

(b) If in the opinion of the board the grant of such permission to any such practitioner is likely to cause administrative difficulties in the working of the hospital the board may refuse the application or may grant it in respect only of a specified part of the hospital.

(c) If in the opinion of the board any medical practitioner to whom such permission has been granted has caused administrative difficulties in the working of the hospital or in any portion thereof the board may revoke its permission, and thereupon such practitioner shall have no right to attend patients in the hospital.

(2) Notwithstanding anything in this regulation contained, no permission as aforesaid shall be refused or revoked by the board or shall be granted to a medical practitioner to attend patients in a specified portion of the hospital only, without the previous sanction of the Administrator.

Since the publication of the above-mentioned regulation a controversy has arisen in respect of its interpretation. The regulation lays down that before a doctor who is not on the staff of a hospital may attend a fee-paying patient at that hospital he must apply for permission to the hospital board, which, with the consent of the Administrator, may refuse to grant him permission if, in its opinion, the doctor in question "is likely to cause administrative difficulties in the working of the hospital." In view of the recent trouble at Mafeking, reference to which is made in the *BRITISH MEDICAL JOURNAL* for June 11th (p. 1078), one interpretation placed on this clause is that it is designed to apply what is virtually a colour bar. In the public press an attack has actually been directed against the Administrator of the Cape Province for taking what is alleged to be ultra vires powers in order to defeat the old traditions against discrimination on the grounds of colour. Interviewed by a representative of the press as to the views of the medical profession on the subject, the President of the Cape Western Branch of the Medical Association of South Africa (British Medical Association) stated: "As a matter of fact the profession opposed the draft ordinance originally proposed by the Administrator, as we felt strongly that it was entirely wrong principle to make any discrimination against a doctor who has been fully trained and licensed, for any reasons which could not be defined clearly. Then the whole matter was carefully considered by the Federal Council of the Medical Association of South Africa at Durban, which passed the following resolution and formally transmitted it to the Administrator:

"The Council is of opinion that it is eminently necessary that boards of public hospitals be empowered to withhold the privilege of attending upon patients in the hospital—or specified portion thereof—from any person when, in the opinion of the board, or that of an official duly authorized thereto by a resolution of the board such attendance might result in or be likely to cause difficulties in the efficient administration of the hospital. The practitioners from whom the privilege of attendance on patients is so withheld shall, however, have the right to appeal to the provincial administrator whose decision shall be final.

"It will thus be seen," pointed out the President, "that the Administrator is really carrying out in effect the recommendations of the Medical Association. In fact, we found him extremely willing to meet the views of the medical profession as far as lay in his power. All that this regulation insists upon is that any person who by his action causes administrative difficulties may, if it is considered necessary, be deprived of the privileges of the hospital. It does not refer to a colour bar at all." As

far as the Mafeking Hospital is concerned, following the gazettement of the new regulation, all the members of the staff applied for permission to attend their patients as laid down by the included ordinance, with the sole exception of the native practitioner whose action originally brought about what was virtually a strike on the part of the nursing staff of the hospital. More recently, however, the native practitioner in question has made application to the Mafeking Hospital board for the necessary permission, but this, it is understood, has been refused. What the outcome of this latest development will be remains to be seen, but there would appear to be no redress for a practitioner thus refused permission unless the ordinance is held to be ultra vires by a court of law.

### PRESENTATION TO DR. A. MARIUS WILSON

After close on thirty years in the service of the railway administration as medical officer at Cape Town, Dr. A. Marius Wilson recently retired on reaching the age limit. As a token of appreciation on the part of the members of the railway sick fund of services rendered over so long a period a presentation was made to him to mark the occasion. This took the form of a bookcase, a chair, a writing desk, and an inkstand. Mr. Potter, assistant general manager, South African Railways, in making the presentation, assured Dr. Wilson that they all very much regretted losing him, for at all times he had proved himself to be a faithful adviser and friend. While always sympathetic to the genuine sufferer, yet betide the misadventurer, who got very short shrift from him. Mr. Coppin, nominated member of the sick fund board, associated himself with Mr. Potter's remarks, while Mr. McDowell, secretary of the board, and Mr. McMillan also spoke. Dr. Marius Wilson, in expressing his thanks for the handsome gifts, found it difficult to put in words his appreciation of the spirit which had prompted the presentation. He related reminiscences which recalled incidents taking place at different times during his thirty years' work amongst the railwaymen of the Union. This period he would always look back upon with the happiest of thoughts. His only regret was that so many of the old faces had passed away. In addition to those mentioned is being present at the ceremony were Dis Jones, Dwyer Chinnock, Johnston, Lawrie, and Greys, colleagues of Dr. Wilson, as well as the majority of the officials and elected members of the sick fund board.

### UNION OF SOUTH AFRICA CENSUS 1926

The census figures recently published by the Office of Census and Statistics show that the European population of the Union in 1926 amounted to 1,676,660, comprising 819,742 males and 856,918 females. This represents an increase of 157,172, or 8.31 per cent, during the five years since the last census, taken in 1921. The preponderance of females over males has been reduced from 94,000 in 1911, and 45,000 in 1921, to 37,000 at the present time. Almost one-half of the population are under 21 years of age—thus of females 404,988 are under and 451,930 over 21 years of age; of males 393,656 are under and 426,086 are over 21. The number of males and females above the age of 75 and over is almost equal there being 8,043 males and 7,990 females, but the number of married women is only 1,529, compared with 4,784 married men over the age of 75. The total number of married men shown by the census is 307,250, while there are 305,346 married women. The number of widows, however (45,340), is nearly three times the number of widowers, which is only 16,810. Taking the married by age periods, it is seen that of males only 194 appear between the ages of 15 and 19, whereas in the same age period no fewer than 4,990 females had entered into matrimony. Three women had married at ages between 10 and 14 years. Between the ages of 25 and 29, 27,640 men are recorded as married, as compared with 43,964 women. Between 30 and 34, 43,074 men and 43,312 women were married. The number of married males reached its zenith between 35 and 39 (44,565), during which period 8,531 appear as unmarried. At 65 to 69 years of age, 11,520 men were married and 1,286 not married, and in the same period 6,401 women were married, which number

approximately to the 6,644 married miles between the ages of 70 and 74. Divorces among men are first recorded in age period 20 to 24, when 26 appear but the figures soon increase, there being 178 men divorced at ages between 25 and 29. The peak is reached with 428 divorces among men between 45 and 49 years of age. The total number of divorced men in the census is 2,570, comprised with 2,667 divorced women. Twelve women of ages between 15 and 19 are set down as divorced, the peak figures being reached among women with +41 at 30 to 34 years of age, 420 at 35 to 39 years, and 401 at 40 to 44 years.

#### MEDICAL ASSOCIATION OF SOUTH AFRICA (B.M.A.) CAPT WESTERN BRANCH SPECIAL COUNTY MEETING

During the past year or two the programme for the session of the Cape Western Branch of the Medical Association of South Africa (British Medical Association) has included a clinical meeting at some centre in the country districts. In 1925 the inaugural meeting, of what promises now to be an annual event took place at Paarl and was attended by a very large number of members, those from Capetown predominating. In 1926 Malmesbury was the venue, and once again a most successful meeting, both in point of number of members present and quality of the contributions made, had to be recorded. These meetings are proving themselves of value in more ways than one. Not only is opportunity given for town and country members to meet on common ground when matters of mutual interest can be discussed, but the social side also, is not neglected, new friendships are formed and as often as not old ones renewed. From the point of view of the townsman, confined to his consulting room day after day, such an outing is an event to be looked forward to, affording him as it does a chance of becoming more familiar with the rural districts whence come so many of his patients.

This year the Annual Country Meeting took place at Somerset West, a prosperous town situated close by the shores of False Bay, some 33 miles from Capetown on the evening of Friday, October 7th 1927. Prior to the clinical meeting the members of the Association present were entertained to dinner by the officials of the Cape Explosive Works, Ltd. Some sixty members and friends sat down to dine in the commodious recreation hall belonging to the works under the chairmanship of Dr. Gutsche, principal chemist to the company. A guest of honour present was Sir George Cory, official historian to the Union Government while all the local medical and dental practitioners were invited as guests of the company. After the customary formal toasts had been duly honoured the guests were welcomed by the chairman in a well chosen speech. Mr. T. Lindsay Sandes, vice-president of the Cape Western Branch of the Medical Association who deputized for the president Dr. James Luckhoff unavoidably prevented from being present responded on behalf of the guests in his usual happy manner. Among others who spoke were Sir George Cory, who after dinner oratory is always delightful, Professor W. A. Jolly, Dean of the Faculty of Medicine in the University of Capetown and Mr. C. C. Scully. Two dinner concluded an adjournment was made to the meeting hall where several interesting cases were shown by Dr. Griffiths, medical officer to the Cape Explosive Works and Dr. Isaacson, a local practitioner. Some very useful discussion followed, concluding the business of two evenings. Although many members were compelled to return to Capetown the same night not a few remained until the following day and were well rewarded for their trouble in so doing. The morning was spent in a visit to the estates of Lourensdorp and Vergelegen, the properties of Mr. J. W. Jagger and Sir Lionel Phillips respectively, at the last-named place members and their wives were entertained to tea on the picture que terrace of the old Dutch homestead. The afternoon was occupied by a tour of inspection to the Steenbras Waterworks, the vast undertaking of the corporation of the city of Capetown lately completed where the main reservoir formed by building a retaining wall across a narrow mountain gorge extends for some miles up the valley and impounds 6,000,000,000 gallons of water. The latter after filtration is conducted by two great pipe lines to the city, a distance

of over forty miles and serves the needs of a population which at the present time numbers close on 500,000. Great credit is due to Dr. Griffiths, who was responsible for arranging so instructive and enjoyable a programme. There is little doubt but that after the experience of the past three years the country meetings will become annual events in the activities of the Branch.

## India.

### TRAVELLING DISPENSARIES IN THE CENTRAL PROVINCES AND BERAR

ADVERSE climatic conditions during 1926 in the Central Provinces and Berar resulted in an increased mortality due to various diseases, particularly plague, cholera and malarial tuberculosis increased and more sanatorium accommodation appears to be necessary. Lieut. Colonel H. G. Stiles Webb, I.M.S., in his annual public health report, comments on the valuable services rendered by travelling dispensaries in militating against these and other diseases, often under very difficult conditions. Twenty nine of these dispensaries were at work during the year, and visited 6,216 villages, treating nearly 104,000 patients, the majority of whom were suffering from malarial diseases or the digestive and respiratory systems, and skin and eye trouble. In addition to 26,000 antiplague and 8,000 cholera inoculations, 1,418 minor operations were performed and 51,000 school children were examined. The vaccination and vital statistics were checked in the different villages visited and reports were prepared on the local water supplies and general sanitation. Many public lectures were given particularly on child welfare and the prevention of plague, cholera, small pox and malaria. A special effort was made to check the prevalent evil of opium administration to infants. Commenting on the public health work in this part of India, Lieut. Colonel Stiles Webb expresses the opinion that helminthic infection is very common in the case of hookworm he puts the incidence at 20 per cent, while that of roundworm is 15 per cent. He emphasizes the urgent need of establishing a public health institute which could take up the study of this infection and advise also as to the best lines of attack on the very high infant mortality rate which compares unfavourably with other parts of India. The institute might also take up the study of tick fevers and intestinal infection. Plague appears to be becoming endemic in Jabulpore and the local circumstances favouring this need investigation. Co-operation between the public health and veterinary services is advocated with a view to the elucidation of such matters as the relation between tick diseases in man and animals and also the spread of tuberculosis.

### MEDICAL PROGRESS IN BHOPAL

The new Prince of Wales Hospital in Bhopal was opened on October 31st by the Begum accompanied by her son the present Nawab. The pre-existing hospital was opened in 1878 when the average daily attendance was about ninety three, it has gradually expanded since that time and gained in popularity, the present daily attendance having risen to over 500 and an annual grant being received from the State for its maintenance. The Begum has always taken a very active interest in the work of the hospital since its institution, and contributed generously towards the provision of the new building which has been erected by the Public Works Department of the State or Bhopal at a cost of about £50,000. The hospital includes an up-to-date operating theatre, well equipped wards for patients, an x-ray plant with a complete electrotherapeutic apparatus, and a good bacteriological and pathological laboratory. It is hoped to add departments for dentistry, ophthalmology, and otolaryngology in the future. At the opening ceremony the Nawab appealed for continued and increased financial support, he referred particularly to the need of providing a ward for paying patients, and to obtaining an expert medical staff. Other schemes under contemplation for the improvement of medical facilities throughout the State include a supply

called upon to accept the responsibility for nursing care in the strict sense which devolves upon qualified mental nurses. They will, however, be persons of proved fitness, temperamental and other, for association with the insane, and will be competent, under the supervision of trained nurses, to have the care of certain types of mental cases which do not require skilled nursing. They will be known as "hospital assistants," and it is thought that their numbers should not be more than 20 per cent of the nursing staff. The commencing rate of remuneration of the new grade will be the same as that of probationer nurses, but the first increment will not be given until the completion of three years' service, and will depend upon the employee's efficiency in first aid. In no event will they be put permanently or temporarily in charge of wards by day or night. The proposal that such a grade be created is made in the first instance by the Departmental Committee on Nursing in Mental Hospitals, and was afterwards endorsed in the report of the Royal Commission on Lunacy and Mental Disorder.

ROYAL ALBERT INSTITUTION, LANCASTER

Open-air verandahs have been constructed at the Royal Albert Institution, Lancaster, in the course of the last few years, and during the last twelve months a most useful one has been placed on the south side of the girls' wing, providing accommodation for open-air walks, instruction classes, and games. An artificial sunlight apparatus has been installed in a room in the tuberculosis home. The Royal Albert Institution, which was established in 1864 for the impropriate feeble-minded of all classes in the seven northern counties, has found the pressure on its accommodation very great during the past year. Since its commencement 4,370 patients have been admitted, many of whom have been considerably improved, and about 10 per cent have become practically self-supporting under friendly supervision. It is subject to inspection by the Commissioners of the Board of Control and by deputations from boards of guardians and local authorities, under the Mental Deficiency Act. The sixty-third annual report, which has recently been issued, contains a detailed account, with pictures, of the valuable work that is being carried on. The institution, which is situated about a mile from Lancaster, is supported by voluntary contributions, and there is accommodation for paying patients.

Disinfection of the public swimming bath in Eccles, which contains 63,000 gallons of water, is effected by passing the water daily through two filters, it is then returned to the bath after re-aeration and warming to 75° Fahrenheit. The surface of the water is skimmed each morning and the sediment removed from the floor of the bath. In his annual report for 1926 Dr J E Spence, medical officer of health for Eccles, states that the bath was last filled in January, 1923, a small quantity of water having been added each day to replace wastage, since that date the bath has been used by over 200,000 bathers. Bacteriological examinations are made four times a year, samples of the water taken in February and June were almost sterile, but those examined in August and November were not so good, owing to some of the cones at the base of the filters being defective. At the beginning of the present year a swimming bath was opened for women, it contains 46,000 gallons of water.

ST. JOHN'S HOSPITAL, BIRMINGHAM

Reference is made in this column on November 26th (p. 1004) to the opening of the new surgical block of Queen's Hospital, Birmingham. Five beds in the new extension have been endowed by the Birmingham City Police Force, the Hulford Cycle Company, Messrs Joseph Ivimey, Mr W J Adams, and the honorary medical and surgical staff of the hospital. These beds were formally dedicated by Sir Charles Hyde, president of the hospital, on December 13th, and during the same proceedings it was announced that the employees of Messrs Davenport had given the money to endow another bed. The debt on the extension has been very materially reduced by these gifts to about £12,000.

## Scotland.

### Gynaecology Appointments in Edinburgh

Dr JAMES HAIG FERGUSON, who, on December 15th, retired under the age limit from charge of wards in Edinburgh Royal Infirmary, was on December 19th elected by the managers to the post of consulting gynaecologist to the Royal Infirmary. Dr Haig Ferguson had acted as house physician to the institution in the year 1884-85. In 1906 he became a member of the honorary staff as a consultant gynaecologist, and in 1921 he was promoted to the charge of wards. A record of the invaluable services which he had rendered to the Royal Infirmary was submitted. Dr Hugh S. Davidson was appointed to charge of wards in succession to Dr Haig Ferguson, and Dr Douglas Miller, F.R.C.S. Ed., was elected to the vacant post as assistant gynaecologist to the institution. At a meeting of the board of Edinburgh Royal Maternity and Simpson Memorial Hospital, Dr Hugh S. Davidson was appointed ordinary physician to this institution in the room of Dr Haig Ferguson, who had retired under the age limit, and who was appointed honorary consulting obstetrician to the hospital. The directors of the Chalmers Hospital have appointed Dr Douglas Miller gynaecologist to the hospital to fill the vacancy caused by the retirement of Dr Davidson on his appointment to the Royal Infirmary, and the board of management of the Dermocess Hospital has appointed Dr E. F. Fisher, F.R.C.S. Ed., as gynaecologist to this hospital in succession to Dr Davidson.

### Longmore Hospital

The annual meeting of the Royal Edinburgh Hospital for Incurables was held in the Longmore Hospital, Edinburgh, on December 9th. The report showed that the average daily number of patients under treatment had been 265 during the past year. The ordinary income for the year had been £12,565, and the ordinary expenditure £20,269, constituting a debit therefore of £7,640 which had been met out of capital. The average cost per occupied bed for the year had been approximately £69, as against £85 for the preceding year. The increase being mainly explained by the fact that the coal bill had been higher by £1,032 than in the preceding year while the increase in the cost of food had been only £81. The hospital had to a great extent, relieved the general hospitals by admitting cases of incurable disease which were in urgent need of hospital treatment but which could not be retained indefinitely in the general hospital. The chairman, Sir Henry Cook, moved the adoption of the report and appealed for increased subscriptions to the hospital. The Very Rev. C. L. Watt, who seconded the motion said that those of them who saw from week to week the difficulties that were entailed by protracted illness in small and congested houses could fully realize something of the benefit that this hospital conferred upon the hundreds who found shelter and care within its gates. It should be realized further that the gratitude that many of these thanks to unnamed investigators, were long received from the category of incurable disease. This hospital was an institution of which the city ought to feel proud, and he was sure it would never lack support and practical encouragement from the citizens.

### GLASGOW WESTERN INFIRMARY

The annual meeting of Glasgow Western Infirmary was held on December 22nd. Colonel J. A. Polburgh, chairman of the board of managers, presided. The chairman stated that the financial figures for the year just past were very much the same as those for the previous year. The ordinary expenditure being approximately £23,000. The income amounted to about £21,800, or about £7,600 less than in 1926. An appeal had been made to the subscribers to increase the ordinary income so that the deficit between it and the ordinary expenditure might be materially reduced. It was announced that the David Elder Infirmary at Govan would be ready as an auxiliary hospital for patients early in 1928, and this would bring a

casualty or relief to the pressure which had been felt in the Western Infirmary for many years. The prizes and medals awarded by the nurses for examinations were distributed by Mrs. David Wilson, wife of the Lord Provost of Glasgow.

### Diphtheria Death Rate in Edinburgh

A table has been published showing the number of deaths from diphtheria in the city of Edinburgh for the years from 1894 to 1926. In 1894 the deaths from this cause totalled 141, but the number gradually decreased till 1908 when there were only 25 fatal cases. Thereafter deaths rose somewhat so that in 1912 there were 31 deaths, in 1914 97, and in 1915 117 deaths. During the next six years the number fluctuated between 60 and 80. In 1925 it was 84, and in 1926 fell to 43. As the population of the city was increased by about 100,000 in 1920 owing to the expansion of the city boundaries the figures since that year represent a very considerable diminution. The majority of the fatal cases during the period of thirty years have been mainly in children under 5 years of age, and very few deaths over the age of 15 years have been recorded.

### QUEEN VICTORIA'S JUBILEE INSTITUTE FOR NURSES

The annual meeting of the Scottish branch of the Queen Victoria's Jubilee Institute for Nurses was held in the City Chamber, Edinburgh, on December 16th. Lord Provost Stevenson presided, and remarked that in the preceding year 102,000 cases had been nursed by members of this institute in Scotland. These cases had involved 1,872,000 visits. He regarded it as a great achievement that in these days of dull trade and unemployment £80,000 could have been raised in Scotland for the Queen Alexandra Memorial Fund to augment the reserves of this institute. Dr Thomas F. Dewar, C.B. or the Scottish Board of Health in moving the adoption of the report spoke of the gradual evolution in the standard of nursing during the past forty years. There was at present in progress in Scotland a considerable change in the relations of the associations which dealt with maintenance of health and the welfare of the sick. A process of evolution was going on almost without legislation. The organization in some countries was, however, far ahead of what it was in others and co-operation between the local authorities and Scottish Board of Health on the one hand and the nurses on the other had been especially beneficial in the outlying regions of the Highlands and islands, where difficulties were greater. It was a statistical fact that the children whose first month of life was supervised by the nurses of the institute had three times the chance of survival enjoyed by children otherwise tended. The adoption of the report was seconded by Mrs. Burnett Smith (Annie S. Swan). A letter was read from H. R. H. Princess Louise, president of the Scottish branch of the institute expressing satisfaction at the improvement in the financial position which had been achieved.

### CENTRAL MIDWIVES BOARD FOR SCOTLAND

At a meeting of the Central Midwives Board for Scotland for the hearing of penal cases Dr James Haig Ferguson, in the chair, it was reported that a certified midwife had been found guilty of attempting to procure abortion and sentenced to twelve months imprisonment and it was resolved that the secretary be directed to remove her name from the roll of midwives and to cancel the certificate and in addition thereto in terms of Section 8 of the Midwives (Scotland) Act 1915, to prohibit her from attending women in childbirth in any other capacity. At the same time it was reported that a certified midwife had been found guilty of performing an illegal operation on a young woman as the result of which the woman died and the midwife was sentenced to three years' penal servitude. Mr. G. B. Davidson, advocate, instructed by Messrs. Lindsay, Co. and Dickson & Co. appeared and made a statement on behalf of the nurse. The Board resolved that the secretary be directed to remove the name of the midwife from the roll of midwives and to cancel the certificate and in addition thereto in terms of Section 8 of the Midwives (Scotland) Act 1915 to prohibit her from attending women in childbirth in any other capacity.

## TROPICAL AUSTRALIA

SIR,—In the BRITISH MEDICAL JOURNAL of September 17th (p. 507) there appeared a reference to the possibility of peopling the tropics with a white race, with special reference to Australia. The note concludes as follows: "Meantime, in North Queensland a great experiment is in progress. Several generations may have to pass before conclusive results can be obtained."

Several generations have already passed, and the result of the experiment so far is most satisfactory. The future must necessarily speak for itself. The essential feature of life in tropical Australia is its almost complete freedom from tropical diseases. There is no incursion of infected native population, and consequently the problem is limited to the consideration of the question: Can heat, and heat alone, cause serious damage to the white race? So far the answer is unequivocal. Apparently there is no other tropical country on the globe from which tropical diseases are absent. It is this circumstance which explains the popular misunderstanding of the Australian position. Beliefs of the kind do very hard, and one is reminded that more than a century ago apparently sensible Englishmen predicted that a healthy white race could not be reared in the latitude of Sydney. The facts speak for themselves. The population of tropical Queensland increased 15.28 per cent during the decennium 1911-21, whereas in the Commonwealth as a whole the increase was 9.11 per cent in rural areas and 19.10 per cent in provincial urban areas.

The vital statistics are striking: the birth rate is higher than in any other part of Australia, and the total death rate is 7.4, as against 9.87 for the Commonwealth. The infantile death rate for the whole of Queensland (which lies north of the 29th parallel) was lower than that of the Commonwealth in nine out of the ten years. The infantile mortality of tropical Queensland is lower than that of the whole of Queensland. It follows, therefore, that residents of tropical Queensland have a better expectation of life, whether in infant or adult life, than anywhere else in Australia, or, indeed, almost anywhere else on the globe. So far elaborate physiological investigation has failed to disclose any serious organic changes in residents of tropical Queensland. The results are the more remarkable, for until recently neither the housing nor sanitation in that country was such as to commend admiration. The literature on the subject is now extensive, and a number of the references are set out by me in *United Empire* of July, 1927, the journal of the Royal Colonial Institute, London.

In my judgement some time must elapse before an educated public realizes that in the tropics it is disease that does the damage, and that at any rate at first unpleasant, but with sensible adaptation and a century of settlement mitigated. Newly-thought-out ideas that no serious ment in tropical Queensland indicated that no serious organic damage need be anticipated. I am, etc.,  
J. W. BARNETT  
Melbourne Nov. 8th

## TREATMENT OF CANCER BY RADIUM

SIR,—When a gynaecologist is consulted by a patient with carcinoma of the cervix it is his solemn duty to advise the method of treatment which has the greatest chance of curing the condition—disputing, operation, or radium—and our present difficulty is that whilst we have definite statistics of the result of operation, we have none in this country for radium.

For the operation many foreign statistics are available, and in this country Berkeley and Bonney published statistics on a five-year basis in 1916, Bonney on a five-year basis in 1921 and on a ten-year basis in 1927, and in this year I published mine on a five-year and seven-year basis. At the end of five years Bonney had 39.7 per cent, and I had 39.5 per cent alive and well, figures sufficiently close to show that about 40 per cent of the cases sufficiently reason to expect to be alive after five years from Wertheim's operation in the hands of those who regularly perform this operation.

The Manchester Radium Institute has been treating the cases for twelve years and the London Radium Institute for a longer period, so it is surely not asking very much of British radiology to publish statistics on, at any rate, a five-year basis.

Granted, the largest percentage of these cases are advanced inoperable ones, but every gynaecologist refers some early cases for radium treatment because the general condition of the patient does not warrant such a severe operation. When I refer such a patient I always label it as an operable case, and presume other gynaecologists do the same, or, if not, this question could easily be asked, and so a record kept at the institute of these operable cases. It is the result on these cases which we desire and require if we are to give the best advice to our patients.

Inoperable cases I always refer for radium treatment, how far these are benefited hardly enters this discussion, what we want is the result of radium treatment after five to ten years upon operable cases.

The letters of Drs. Forsdike and Birkett are not in the least helpful.

Every gynaecologist is familiar with the statistics of Stockholm and New York, but we are treating cases in England and we have a right to know, before we send early cases for radium treatment, whether English radiologists are obtaining results which are in any way comparable to these or to the figures published by Berkeley, Bonney, and myself. If Dr. Birkett desires I will gladly publish the results of operable cases I have referred to the Radium Institute, so far I have refused, as I was in hopes, from the much larger figures at his command, that he would show much better results—I am, etc.,

Manchester, Dec. 20th

WM. FLETCHER SHAW

SIR,—In your interesting leading article of December 10th on late recurrences of cancer you state that "the undoubtedly good effects of radium and a rise in cutaneous malignant tumours seem to be due in the main to the stimulation of fibrous tissue with its indirect action rather than to selective lethal action on the cancer cells."

That theory I am glad to say has been proved to be entirely erroneous by Lacisagne in Paris and R. G. Cant in this country. If sections are taken immediately after irradiation the selective action on the cancer cells is very obvious, and there is, of course, at that time no evidence of fibrous tissue.

The error has come about from sections cut several weeks after irradiation, when any cancer cells which may have survived are surrounded by fibrous tissue.

This may seem a very small point, but, as I have mentioned before, our great hope in the future of radiology is in finding out why the radium has this selective action on cancer and other quickly growing tissues, and what are the exact chemical and physical changes that take place in such cells, but do not take place in the less active tissues—I am, etc.,

London, W. I, Dec. 20th

MALCOLM DOWNSON, F.R.C.S.

## THE PROBLEM OF MENTAL DEFICIENCY

SIR,—May I be permitted to point out that the policy for dealing with the mental deficiency problem advocated in the eminent annual report of the Bedford Comtee Mental Welfare Hospital for Children, so far from being "a retrograde," is in advance of that advocated by your correspondent Dr. L. A. PARRY (BRITISH MEDICAL JOURNAL, December 17th, p. 1156), in that the latter appears to favour a policy which was once advocated in the United States, but which has since been discarded by all recent American writers as impracticable and unnecessary. I refer to what is known as the "policy of wholesale segregation." Similarly, in our own country, Miss Evelyn Fox, in a paper she read at the meeting of the British Association at Liverpool in 1923, pointed out that the policy of wholesale segregation may be ruled out at once by the mere consideration of numbers involved—"150,000 at the lowest estimate"—and advocated "restricted segregation" of those who otherwise would be destitute and of those showing persistent antisocial tendencies, with supervision of the remainder in the community.

knew better. She would only have "household" flour, which contained much of the germ and aleurone cells.

The false social *cachet* which has clung to the colour of bread, though it did not deviate her from the wholesome tradition, deceived the artisan's wife, and does so still, and among the "circumstances of modern civilization" are the modern miller's sixteen pairs of steel rollers, which eliminate, as of old, the germ and the other parts of the grain that hold the "water-soluble B."

No one doubts that a single action a day is so common as to be the general rule. Whether, with a less sophisticated diet, it would be, whether it is healthy that it should be, whether a higher plane of bodily efficiency and a clearer-headed mentality would be maintained if it were not, and if, instead, two actions were the rule, seem to be questions which are at least arguable—I am, etc.,

Holmes Chapel, Cheshire Dec 6th

LIONEL JAS PICTON

### THE WEIGHT OF THE BRAIN AND MENTAL ABILITY

SIR,—I was much interested in Sir Arthur Keith's article on the brain of Anatole France, and in his remarks with regard to mass of brain and complexity of mental reaction (December 3rd, p. 1048).

The weight of this brain, 1,017 grams, is certainly remarkably low, and is no greater than that of many mentally defective people. The brain of a cecitin, whose mentality was hardly equal to that of an animal, weighed more than this—that is, 1,033 grams—though the cecitin's weight was only 2 st 4 lb. A great mass of brain does not necessarily signify even normal intelligence, and the reverse may be true, although about this there is little information available.

I have recently examined a brain which weighed 1,670 grams—that is, about 300 grams greater than the average. It was from a case of pituitary infantilism with pronounced mental defect, and as the patient only weighed 5 st the increase could not be ascribed to an increase of the "corporeal concomitant" element. A superficial examination of this brain, apart from the clinical history, might have led to the conclusion that it was highly developed. Preparations such as Weigert-Pal stained more readily than usual. Chemical analysis showed, however, that the amount of phosphorus compounds was only about half that in the normal brain. Even, therefore, when the architecture of the brain is normal, there may be some defect in another direction impairing its activity.

Another point of view that may be raised is that there are areas of the brain relatively undeveloped as regards function, although it is impossible to detect this by any laboratory method. In most people the left hemisphere is functionally rather more highly developed than the right—for example, speech is almost entirely a function of certain cortical areas on the left side of the brain. Yet the predominance of the left hemisphere in this respect is not accompanied by greater complexity of histological structure of these areas compared to similar ones on the right side of the brain. There is not any difference to be ascertained by chemical analysis, nor is asymmetry of the brain a common phenomenon.

One may imagine that the brains of people of little mental ability, though perhaps of average weight, may possess a relatively greater number of non-functioning though anatomically perfect areas.

Finally, one may find an analogy between the brain and a musical instrument. The excellence of the music produced does not depend only on the use of a fine instrument, although obviously this is an advantage—I am, etc.,

ELIZABETH COMPER EAVES

The University, Sheffield, Dec 4th

### TREATMENT OF PROSTATIC ENLARGEMENT

SIR,—The letter of Sir Thomas Cray Evans in your issue of December 10th (p. 1114) invites comment.

He commences by stating that the death rate of prostatectomy in the large general hospitals is 40 per cent. (He quotes someone else's statistics without giving the year

in which they were compiled—it is impossible to suppose that they refer to the present year.) He then uses these mortality figures to suggest that the general surgeon is a dangerous fellow to employ for such an operation. For the performance of the operation, he continues, a special knack or gift is required, "which is only acquired by, or bestowed upon, individual surgeons, who eventually specialize in this particular branch of surgery." One may be pardoned if one is led to infer that the writer of that letter is himself one of those highly gifted few.

Surely there is nothing mysterious about the operation of suprapubic prostatectomy. It is often very simple, sometimes (as in other operations) it is really difficult. And it depends for its success as much on the preliminary treatment and after-treatment as on the operation itself.

Although those engaged in general surgery acknowledge with gratitude and admiration the help they derive from others whose research work and wide experience in any special subject has added to the sum of our knowledge, yet I am sure the latter would be the last to claim that in their hands, and theirs alone, any given operation could be safely and properly performed. As a matter of interest I have looked up my own books, and find that the last forty-four cases of prostatectomy have been performed without a death. I quote these figures in no spirit of boasting, and know very well that one may have had a run of luck which may suddenly be badly broken. But, if an ordinary surgeon can get results of this kind, how is one to credit the fantastic figures which Sir Thomas Cray Evans quotes, and what measure of justice does he mete out to the general surgeon when he would deprive him from performing this operation? It would be interesting to know Sir Thomas's own statistics—I am, etc.,

Sussex, Dec 12th

PROVINCIAL SURGEON

### THE ETIOLOGY OF ECTOPIC PREGNANCY

SIR,—Dr Douglas, in his paper on ectopic pregnancy published in your issue of December 10th (p. 1074) has particular stress on the mechanical factor (obstruction in the tube due to previous inflammation) as the cause of the arrest of the ovum in the tube. The comparatively small number of cases in which evidence of old salpingitis is found (much smaller, in my experience, than the 50 per cent. he mentions) suggests that this explanation is not likely to account for all or even the majority of cases.

The view that I have held for some time—but with a clearer understanding of the details since reading Dr W. E. Dixon's paper on ovarian secretion published in the same issue—is that termination of pregnancy in the tube is due to the same cause that brings about the termination of pregnancy in the uterus, whether it full time or prematurely—namely, the defective functioning or involution of the corpus luteum.

It is known that failure of the secretion of this structure results in the cessation of all changes associated with pregnancy, amongst which we must surely include the mechanism by which the fertilized ovum is conveyed from the abdominal ostium to the uterus. If the defect in the corpus luteum is primary, or occurs so early that the ovum is still in the tube, its onward progress will be delayed or arrested, though development may continue. When failure is complete muscular contractions occur in the uterus (as at full term) and in the wall of the tube, with the result that the decidua is separated and haemorrhage takes place from the uterus and in the tube. The tubal contractions cause the severe pelvic pains, and they are strong enough to expel the ovum and clot half-way through the abdominal ostium, or to rupture the wall of the tube if it has been weakened by the developing ovum.

I do not claim that this explanation accounts for all cases of ectopic pregnancy. Ovarian and primary abdominal pregnancy do occur, and the occurrence of a "false labour" at full term is evidence that the corpus luteum has been active during pregnancy in these cases. But it does explain the simultaneous occurrence of haemorrhage from the uterus and in the tube which is difficult to account for in any other way—I am, etc.,

Leicester, Dec 11th

T. C. CRAMP

## Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

### Prorogation of Parliament

WHEN Parliament was prorogued on December 22nd until February 7th the Royal Assent was signified to the Nursing Homes Registration Act, Mental Deficiency Act, Landlord and Tenant Act, Unemployment Insurance Act, Road Transport Licensing Act, Destructive Insects and Pests Act, Explosives Act, Continence Act, Medical and Dentists Acts Amendment Act, Protection of Animals (Amendment) Act, Royal Edinburgh Hospital for Mental and Nervous Diseases Order Confirmation Act and to other measures.

In the King's Speech proroguing Parliament one passage ran: "Striking progress has been made during the past year in providing housing accommodation for the people and the number of houses completed in England and Wales since the Armistice now exceeds 1,000,000. During the past year a greater number of new houses have been completed in Scotland than in any previous year. Substantial progress is also being made with the clearance of insanitary areas and the rehousing of displaced tenants."

### Nursing Homes Registration Bill

On December 21st the House of Lords went into Committee on the Nursing Homes Registration Bill. On the motion that the Bill go into Committee Lord Charnwood said he had just received a statement that objection to the proposal to delegate powers under the bill from county council to other local authorities was taken by the Incorporated Midwives Institute, the College of Nursing, Queen Victoria's Jubilee Institute and the Central Midwives Board. Lord Charnwood said he understood any reference of the clause would upset the agreement reached between two other interested bodies—the County Councils Association and the Municipal Corporations Association. In the negotiations between the three bodies first named and the Ministry of Health some understanding had arisen with the result that the bill in the form it now was came as a surprise to those who being responsible for the framing of the measure, or the country had one right to a voice in the matter. He asked the Government whether it would not bring the bill before the House of Lords early next session. Viscount Haldane declined from this suggestion. There might not be time for the bill in the House of Commons next session. He was anxious to get nursing homes inspected as soon as possible. Lord Salisbury said it gave him considerable anxiety after years of legislation nearly completed but a great body of opinion in the House of Commons was anxious for the bill as was the Minister of Health. The House then went into Committee on the bill.

On Clause 7 (power of the Minister to exempt Christian Science nursing home) Viscount Falmouth moved an amendment to provide that the Minister of Health might at any time inspect any nursing home to which this exemption applied and might refuse exemption or withdraw exemption on the ground that provisions which the bill laid down for nursing homes generally were not observed. He remarked that under this amendment home used by Christian Scientists would be liable to inspection for the experience and reputation of the person in charge for general sanitation and cleanliness and also in regard to the question of midwives. Earl Russell who had an amendment for the omission of Clause 7 said that for the convenience of the House he would discuss it then. He had already drafted an alternative clause. He saw there might be a case for exempting from the bill and particularly from its medical provisions a body which did not receive medical treatment but he could not see why this should be limited to one particular sect. They had the Peculiar People in this country long before Mrs. Eddy. He suggested its substitution for Clause 7 as a new clause to read:

The Minister of Health may grant exemption from the operation of this Act in respect of any nursing home which he is satisfied is being carried on without medical or surgical treatment. Such exemption may be complete or partial and shall remain in force for one year. No order of the Minister shall exempt a nursing home from the requirements or any by-law made under Section 4 (1) (b).

Earl Russell explained that the provision referred to required a report to be made of any death in a nursing home. Deaths in a nursing home in the absence of medical treatment ought to be reported and in any case the requirements of that provision ought not to be the subject of exemption. He added that his proposed clause concluded thus:

An exemption granted under this section in respect of a nursing home may at any time be withdrawn by the Minister if it should appear to him that the conditions have changed.

He said he had been informed that the objection of the Ministry to the wider terms was that they might let in undesirable bodies. He desired the bill to pass and thought the clause he proposed would not imperil the chances of the measure in the Commons. Viscount Alder and Lord Le was authorized to say that the Christian Science movement was willing to accept Viscount Falmouth's amendment. The only point which the Christian Scientists asked for was exemption from the obligation to have in charge of all their homes or institutions a duly qualified doctor or a duly qualified medical nurse. Neither the medical profession nor Christian Science would gain if Parliament insisted that they

should try to run an institution jointly. The Christian Scientists had always tried to explain that they would welcome all forms of inspection.

Lord Haldane said the practical question was whether Parliament was to have this bill or not. He wished to pass the bill and was prepared to accede to logic to do it. Therefore he was against this amendment.

Earl Beauchamp said it seemed important that the bill should be amended. Of those before the House he preferred Lord Russell's and would vote for it.

Viscount Gage for the Government and Christian Science was not merely an unorthodox method of treating the sick, it professed to be a religion. In that respect it could be distinguished from other unorthodox methods of treatment. No other sect whatever its beliefs thought it worth while to submit them to the select Committee on Nursing Homes. The opinion of the Ministry was that if Christian Science homes were not to come within the purview of the bill there must be an exemption clause. The Minister of Health thought it was not in accordance with the principle of religious toleration to refuse such a clause. It had been carefully drafted to make impossible the obtaining of exemption by a person who merely wished to use the cloak of Christian Science to carry on an irregular and unregistered nursing home. The Minister proposed in every case to consult the central authorities of the Christian Science Church. The size of that body and the fact that members of both Houses of Parliament belonged to it entitled it to special consideration. It was to be a condition of exemption that the home should bear a distinctive name—Christian Science Lodge. The Minister wished to be entirely free of any responsibility for these homes. He was prepared in the circular for the information of local authorities which would accompany this bill to make perfectly clear the whole object of having the clause was to take away any possibility of the public imagining the homes had any State supervision at all. The Minister was relying on the Christian Science movement for information of irregularities. Two courses were open. The first would be to require the registration and inspection of Christian Science homes in the ordinary way but with some relaxation of the conditions on qualified nurses and doctors. That would imply that the State took some responsibility for the treatment in the homes. They could claim to be regulated and to receive what would be regarded as a State guarantee. The other course which was followed in the clause was to make a patent that no home was excluded. The number of the homes was very small and they were unlikely to compete on any substantial case with ordinary nursing homes.

The Marquis of Salisbury and the Government could not accept an amendment which radically altered this clause. Earl Russell's amendment would compel the Minister of Health to authorize any home which he was satisfied was carried on without medical or surgical treatment. In that case alone the Minister might grant exemption. There were some homes where old people were taken in to die. There was no question about curing them, they just "went" and died. These homes would falsify the conditions of Earl Russell. There might be every kind of neglect yet it would come within the terms of Earl Russell's clause. There was a great deal to be said for Lord Falmouth's amendment. He was not prepared to pledge the Government to it but he did not resist its being put into the bill. If the Minister of Health saw a serious objection when he came to look at it he would move in the House of Commons to strike it out. Peppering to an intervention by Earl Russell the Marquis of Salisbury said the fact that the homes would be connected with the Christian Science Church was in the opinion of the Government a great guarantee or good faith. Under Earl Russell's amendment there would be no guarantee whatever.

Earl Russell said that as for the homes where old people went to die surely they were under medical observation and treatment and were kept as well as they could be kept.

The Marquis of Salisbury and the Government were not well kept. There were a device under which unscrupulous relatives managed to give them else of the responsibility for looking after their old relatives. Homes of that kind ought to be stopped but would be covered by Earl Russell's amendment. Earl Russell said he now saw the point being neglected would give an opportunity for claiming exemption. But had Lord Salisbury overlooked the fact that exemption would be at the discretion of the Minister who would grant it only if satisfied that the home was properly carried on? The Marquis of Salisbury said that under Earl Russell's amendment it would be very difficult for the Minister to refuse exemption on the basis of the home unless the clause had words telling him what to take into account in coming to his decision. Earl Russell had no provided anything of the kind in deciding whether exemption were possible. The Minister would only have to consider whether there was medical or surgical attention. Lord Salisbury contended that either the clause must contain some directing words which would be difficult to frame or else the clause must be a triched to a well known organization which was in a guarantee of good faith.

The Poet then accepted Viscount Falmouth's amendment. Viscount Gage and Earl Russell then supported the amendment. The clause was then carried and the new clause was then proposed. On a division the clause was carried and the amendment moved by Lord Falmouth was added to the bill.

On Clause 9 Lord Charnwood moved to omit the words "power of delegation or power by a committee" to be added to the clause. He understood that in these powers were a large number of cases as nursing homes might be subject to inspection by an independent and a maternal homes to inspect in any other of patients. The bill proposed the medical branch of the nursing profession to only object to the amendment. Viscount Gage said a compromise had been arrived at in the clause.

at after great difficulty by a large number of responsible authorities. The clause now gave the county council power to delegate any of its duties with or without restrictions that that council thought fit. They could make an exception in the case of maternity homes although these might be in the area which was delegated in all other respects to another authority. If the clause were rejected there would be practically no hope of reaching agreement again in the House of Commons.

Lord Charnwood said that out of this unsatisfactory system of dual inspection there might occur, in a home subject to delegation, one inspection under the present bill together with, and possibly conflicting with, an inspection under the Midwives Act.

The Earl of Onslow said the authority, in the case of midwives was the county council or county borough council. The only delegation permitted under Clause 9 was for purposes under this bill. He understood that, as chairman of the Royal Commission on Local Government, he himself was about to receive a letter explaining that, despite the arrangement under this bill, the Government recognized that the whole question was under the consideration of the Royal Commission, and that the Commission would form its own opinion and report in accordance with evidence which had not yet been received.

Lord Charnwood withdrew his amendment.

The bill then passed through Committee without further amendment, was reported, given a third reading, and returned to the Commons.

Later on the same day (December 21st) the House of Commons considered the amendment made by the Lords to the clause of the Nursing Homes Registration Bill respecting Christian Science houses. Mr Chamberlain moved that the House disagree with the amendment. He said that the Marquess of Salisbury had been unable to consult him before accepting it. Christian Science houses were not nursing homes as the term was understood and Mr Chamberlain did not desire that the Ministry of Health should take any responsibility for them. The House of Commons then disagreed with the amendment.

On December 22nd the House of Lords decided that it would not insist on this amendment to Clause 6, and, as stated above, the bill thereafter became law.

#### Medical and Dentists Acts Amendment Bill

The House of Commons, on December 21st, passed the Medical and Dentists Acts Amendment Bill through Committee without amendment, and read it a third time. This bill, which authorizes the new arrangements for transfer of medical practitioners between the British and Irish Free State registers, had already passed through the Lords, and became law on December 22nd.

**Mental Deficiency Bill**—The Mental Deficiency Bill was read a third time and passed by the House of Lords on December 21st, without discussion.

**Lamps on Ambulances**—An amendment added by the House of Lords to the Road Transport Lighting Bill—since become an Act—provides that the Minister of Transport shall have power by regulations to require or permit distinctive lamps to be carried in the case of vehicles used as ambulances and to prohibit similar lamps being carried by any other vehicles.

**Vaccination of Prisoners**—In a reply on December 21st to Dr V. Davies Sir William Joynson Hicks said that in normal times no special steps were taken for the vaccination of prisoners except with convicts sentenced to penal servitude, who, unless they presented good vaccination marks were vaccinated before removal to the convict prison. During an outbreak of small pox in the area where a local prison or convict prison was situated or in areas from which prisoners were received, it was the practice to vaccinate prisoners who had not been vaccinated within recent years. Mr Shepherd asked whether prisoners had any choice whether they would be vaccinated. Sir William said he had never heard of any complaints from them.

**Milk Inspection**—On December 21st Dr Vernon Davies asked whether the Minister of Health was aware that in the county of Nottingham, during 1924, 43 samples of milk were analysed, of which 97.7 per cent were adulterated during 1925, 73 samples, of which 60.2 per cent were adulterated, and during 1926, 62 samples, of which 54.8 per cent were adulterated, and whether he would impress on local authorities that for the health of their infant population they should institute a vigorous campaign against food adulterators by analysing yearly a much larger number of samples. Sir Kingsley Wood said it was the practice of the inspectors in Nottingham to take a large number of samples informally and to carry out rough sorting tests to ascertain where adulterated milk was sold. Formal samples were then taken at these places for submission to the public analyst. The published returns only referred to the latter samples, and the high proportion of adulteration recorded was a natural result. The method was a new one adopted by the county of Nottingham. The Minister of Health would consider whether advice could usefully be given to local authorities counselling the taking of a larger number of samples where past experience showed an adulteration of over 5 per cent in common articles of diet amongst the poor. In a reply to Dr V. Davies on the same question on December 22nd, Sir W. Joynson Hicks said that in the county of Nottingham during 1924 there were 16 prosecutions for the adulteration of milk, in 1925 11, and in 1926 13. In the city of Nottingham and the borough of Newark the additional figures were 17, 4 and 10 for the respective years.

#### Notes in Brief

From 1918 to December 15th 1925 £5,186,833 was paid as compensation for animals slaughtered as a result of foot and mouth outbreaks. The Government is not prepared to offer a monetary reward for an effective remedy or preventive of this disease.

It will be illegal to sell in this country as olive oil the mixed oil composed of olive oil and oil from ground nuts, the production of which has been authorized this year in Spain.

The attention of the Minister of Health has not been drawn to the refusal of the London County Council to licence a new massage establishment. Sir Kingsley Wood adds that he does not think legislation on the subject to be practicable at present.

The Minister of Transport does not see his way to amend the Regulations issued to prevent noise by motor cyclists.

Sir Kingsley Wood again states that approved societies have no power to set up dental clinics.

## Universities and Colleges

### UNIVERSITY OF LEEDS

A MEETING of the council of the University of Leeds was held on December 21st. Professor J. H. Jamieson, Dean of the Faculty of Medicine, was appointed the representative of the University on the General Medical Council. Dr C. W. Young was appointed to the newly instituted chair in diseases of children and Dr J. T. Ingram was appointed lecturer in diseases of the skin, in succession to Dr Veale who is now Professor of Pharmacology and Therapeutics.

A graduation ceremony was held at the Leeds School of Medicine on December 20th. Dr J. B. Baillie, the Vice-Chancellor of the University, presided and reminded the successful students that the public would expect from them vigilant and efficient service on behalf of the public health and the individual welfare. The onus of realization was laid on the initiative and expansion of civilization depended not only on the increase and expansion of general education but also on the maintenance of sound health which was the first of the medical practitioner. As students they must have realized how little exact knowledge there was in the

THE report for 1926 of the Anna Spelman Rockefeller Memorial, of which John D. Rockefeller, jun., is the president, has just been published, and shows that during that year the appropriations made to various institutions was nearly seven million dollars, rather more than two million dollars being payable in that year, the remainder in 1927 and subsequent years. Social sciences, research in institutions in America and abroad, conferences, travelling fellowships, child study and practical education, boy and girl scouts, and libraries were helped by grants.

THE second congress entitled the "Journées Médicales et Veterinaires Marocaines" will be held next Easter, at Casablanca and Rabat. Professor Leichte and others will read papers on the grafting of glands and tissues in man and animals. Professor Calmette will speak on the use of BCG, Dr. Rimmon on murtoxin, Professor Cluchet on mesencephalitis, and Dr. J. Renault on the general hygiene of a large modern town. Excursions will be arranged in connexion with this congress. Further information may be obtained from the general secretary, Dr. Lepinay, Rue de Marseille, Casablanca.

THE mortality in the forty largest towns in Germany was lower in the first half of 1927 than in the corresponding period of 1926—namely, 10.1, as compared with 10.3 per 1,000 inhabitants, the mortality among children under 1 year of age was 1.2 as compared with 1.3, and the mortality from tuberculosis 1.01 as compared with 1.28. The depopulation of rural districts is still on the increase as is shown by the fact that the population of the forty large towns was 16,881,000 in 1926 and 17,360,000 in 1927.

EXTRACTS from the annual report of the Ministry of Health for 1926-27, dealing with the administration of the Poor Law, and including reports of general inspectors of the Ministry, have been issued separately by H.M. Stationery Office for official use at the price of 1s.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square, W.C.1**, on receipt of proof.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are: **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Antiology Westcent, London*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.) *Antiology Westcent London*

**MEDICAL SECRETARY**, *Medicocera Westcent London*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams *Macillus, Dublin*), telephone 4737 (Dublin) and of the Scottish Office, 6, Drumsheugh Gardens Edinburgh (telegrams *Associate, Edinburgh*), telephone 24361 (Edinburgh).

## QUERIES AND ANSWERS

### WINTER MORORING

"CANADIAN" asks whether any reader can from practical experience recommend a radiator heating paraffin lamp—safe, efficient, economical, and not too expensive?

### INCOME TAX

#### Change in Partnership

"W.A.M.W." after his return from abroad, entered his father's firm as a third share partner as from June 1st 1927. As from December 1st his father retired, receiving a lump sum of £300 and an annuity of one third share. What is his liability to income tax?

\* \* \* Our correspondent's earnings are liable as from his return to this country—apart from any other person he did not return for a temporary purpose only. Assuming the amount of the practice profits for 1926 (and, therefore, the amount of the assessment for 1927-28) to be £1, our correspondent's share of the assessment will be ten twelfths of one third of £1. The £300 is regarded as a capital payment and cannot be treated as a deductible expense for income tax.

purposes. The firm, as such, are liable to account for the tax on the whole profits, including that portion paid over as an annuity to the retiring partner, but can claim a corresponding adjustment as between the partners and the annuitant. The most convenient way of dealing with the matter would be to regard him as a sleeping partner for periods subsequent to December 1st 1927, and, as the amount of income tax ultimately payable would not be affected it would seem likely that the authorities would acquiesce in that course.

## LETTERS, NOTES, ETC.

### A DISCLAIMER

DR JAMES LEON, medical officer of the Bolton Road Infirmary, Lincoln, writes: I wish to disclaim all responsibility for the extravagant claims appearing in the lay press on December 21st and other dates with regard to a case of encephalitis lethargica treated at this institution. I can state definitely that these reports were acquired by the lay press entirely from extra medical sources.

### SHOCK AFTER PROTRUSION OF INTESTINES

DR GLO SMITH SOWDEN (L.M.D.) writes: The recent correspondence in the **JOURNAL** on disembowelment and shock has brought to mind an incident related last summer to a colleague and myself by an officer of the Sudan Defence Force who is in charge of one of the most southern posts in the Sudan, and is twenty days' camel ride from the nearest medical officer and five days' camel ride from the nearest white man and has no other white man with him, so he has to be M.O. as well as C.O. One day he espied a Sudanese staggering into the small fort holding his hands in front of his abdomen, and with his jebbah (long loose gown worn by the natives) all bloodstained. Closer examination showed that, wrapped in the folds of the filthy jebbah, were 6 ft. or 7 ft. of intestine protruding from a long, incised wound of the abdominal wall. The man said that he had had an altercation with a fellow villager that morning and had been stabbed in the abdomen with the broad stabbing knife carried by the natives with the result that his bowels protruded. He promptly set off and walked three miles to be attended by the white doctor. He had fainted more than he did the local "bul" in the hospital of the fort, and he was for internal use (1), made a solution of salt and warm water, which he washed the protruding bowels very carefully, and then proceeded to return the intestines to the abdomen with the help of the native sergeant-major. This was safely accomplished, and the abdominal wall closed up. The whole operation was performed without an anaesthetic. The result was even more dramatic than the operation. The man had a rise of temperature for four or five days, but otherwise showed very little trace of what he had gone through. It was with difficulty that he was kept in bed for three weeks, as his one desire was to return and win vengeance on his opponent. This incident is still more remarkable when it is remembered that the resistance of the black races to surgical shock is considered to be very weak, and also when the rough and ready treatment he received is realized. It gives the Latin disciple "furious to think."

### DIARRHŒA SIMULATING FOREIGN BODY IN THE THROAT

DR GAWLEY MADDIN (Education Department of New South Wales, Sydney, Australia) writes: I can corroborate Dr Charles J. Hill Aitken in his report of a case of laryngeal diphtheria simulating foreign body in the larynx (**BRITISH MEDICAL JOURNAL**, September 17th, p. 526). In the winter of 1923 a child, aged about 12 months was brought to the casualty department by its mother who stated that it had "swallowed a bone" while she was feeding it with mutton broth. The child was not very well looked after, and it was impossible to get any more detailed history so that, as far as this illness was concerned, the child had only been sick about an hour when seen at the hospital. In spite of this history the child was found to be suffering with a well marked laryngeal diphtheria, and to my double certainty the larynx and trachea of the child were invaded, but no foreign body of any description was found. The child was eventually intubated and finally a tracheotomy had to be performed, and I think from memory, the child died. I was told at the time by the bonair physician (Dr Margaret Harper) of a case in her experience in which the opposite had occurred: a child was brought to her for what was thought to be laryngeal diphtheria, but on examination she found a foreign body resting in or on the larynx. After all it is to be remembered that sometimes these conditions are mistaken one for the other. The membrane in laryngeal diphtheria acts very much like a foreign body though usually of course the degree of toxæmia leaves little doubt of the diagnosis.

### VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 36, 40 and 41 of our advertisements, columns and advertisements as to partnerships, assistantships, and other vacancies at pages 38 and 39. A short summary of vacant posts notified in the advertisement in the Supplement at page 22.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine.

### 1. Non diabetic Obliterating Arteritis

H. VAQUEZ and J. YACOFF (*Presse Med.*, May 18th, 1927 p 625) report four cases of the chronic form of non senile non diabetic obliterating arteritis, in which great benefit resulted from the administration of insulin. They state that the chronic is the most common form of the disease the acute type, in which both the veins and arteries are simultaneously affected and the subacute variety being rarer. The commencement of the affection is marked by a group of subjective symptoms (sensitivity to cold, numbness of the feet and toes burning sensation of the soles, vague pains on walking), and this stage may last for months or even years. When the disease is established diagnosis is easy. The first symptom is cyanosis of the foot which reaches to the ankle in the erect posture. Intermittent lameness or painful cramp on walking is pathognomonic. The pulsations and oscillations of the posterior tibial and pedal arteries are diminished or abolished. Some times a slight amyotrophy, more often spontaneous pains with nocturnal exacerbations occur in the affected member and frequently painful swellings, which are probably subcutaneous or intramuscular infarcts, appear in the calf of the leg. Unless arrested the disease progresses to serious ischaemic troubles and gangrene moist and massive of the toe, foot or whole limb which necessitate immediate amputation. The authors consider that the disease is probably the result of a trophic trouble of the arterial coats due to endocrine disturbance. Referring to the failure of other methods, Vaquez and Yacoff bring to the excellent results following insulin treatment to its effect on this trophism. Intramuscular or intracellular injections of 10 to 20 chemical units daily for twenty days are recommended then after ten days interval another series is given and this procedure is continued for months or even years till cure is established. The glycaemia should be estimated, if this is low, the dose should not exceed 10 to 15 units. If glycaemia appears local treatment with balsam of Peru or Lucas Championniere's powder should be applied while the general insulin treatment is continued. Despite this, massive glycaemia may supervene but the authors urge patience before operating as cures often occur unexpectedly after a time. Amputation should only be performed where there is danger of septicæmia or shock.

### 2. The Campaign against Tuberculosis

D. JAJA (*Il Morgagni*, April 17th 1927 p 601) discussing the prevention of tuberculosis emphasizes the importance of publishing information about errors of feeding and hygiene and concentrating on the health of children. He states that of the 1,200,000 children born each year in Italy 2,000,000 die within the first three years of life and only 70 per cent reach the age of 5. More than a million children under 3 suffer from intestinal diseases producing conditions favourable to the invasion of tubercle. He thinks that young children should be separated early from infected parents, since among children brought up by tuberculous persons only 3 per cent are infected at the age of 3 months, whereas 50 per cent are found to be tuberculous when 5 years of age. Referring to the Italian emigrants to America who are subjected both on their departure and on their landing to a strict medical inspection he reports that many of those who return to Italy are shown to have contracted tuberculosis. Out of 866,222 persons repatriated from North America in 1919 to 1923 inclusive 4,703 had tuberculosis, of all 317 repatriated from South America from 1910 to 1922 inclusive 955 had tuberculosis. These figures point he considers to the necessity for prophylactic vaccination and he adds that at the third national medical congress at Buenos Aires it was agreed that the vaccine prepared by Calmette and Guérin was mucosely stable and an effective prophylactic against tuberculosis in man and animals.

### 3. Types of Influenza Epidemics

R. FISCHL (*Med. Klin.* April 1927 p 592) compares various influenza epidemics. He states that the outbreak of 1889 was characterized by inflammation of the upper air passage, but the most striking feature was the prostration which followed and which has not been seen since in so intense a form. The epidemic of 1912 was a faint copy of 1889 that of 1918 showed the severe pneumonia resembling pneumonia plague while that of 1923 attacked chiefly the nervous system the cases being almost indistinguishable clinically from encephalitis lethargica meningitis or pseudo encephalitis. In 1927 the infection has been, in his experience of fifty

cases of a much milder type than in any previous epidemic. The disease usually began with a pharyngitis which quickly spread in the trachea, bronchi and alveoli, giving rise to every form of pulmonary complication from capillary bronchitis to multiple pulmonary abscesses in one patient, who became very anaemic, and had intermittent high fever, an enlarged hard spleen and streptococci in the urine and bronchial secretions. One case showed an apical pneumonia associated with marked meningeal symptoms, the cerebro-spinal fluid was clear under marked pressure and without abnormal constituents. Many patients, particularly females exhibited pyuria as an early symptom. Pneumococci were recovered in most cases and occasionally *M. catarrhalis*, but *I. feufferi bacillus* was not found.

### 5. Non syphilitic Genital Spirillosis

J. CANTIN (*Thes. de Paris* 1926 No 472) who records nine illustrative cases, six of which were in males and three in females, aged from 16 to 32 states that non syphilitic genital spirillosis is mainly caused by *Spirochaeta gracilis* *S. rejingensis* *S. phica* *S. balaenitidis* and *S. vineti*. Clinically, it may assume one of the three following forms: (1) single saprophytic spirillo (2) Autonomously pathogenic spirillosis of which the following varieties are described a simple balanitis (Vincent) in which the spirillum is associated with an athero c or anismus the circinate erosive balanitis of Berdat and Baillie in which the spirillum is associated with bacilli and cocci, an ulcero membranous balanitis (Queyrat) in which Vincent's *Spirochaeta* is associated with the fusiform bacilli constituting a vibriosis analogous to that which gives rise to Vincent's angina and ulcero membranous stomatitis (3) Spirillosis associated with hard or soft chancres. In some cases the fusiform spirillum can cause phagedaena. Local treatment with salvarsan preparations is indicated in every case of non syphilitic genital spirillosis.

## Surgery

### 5. Fracture of the Surgical Neck of the Scapula.

A. MAGLILLO (*La Chirurgia degli organi di movimento* April 1927 p 211) finds that these fractures are more frequent than is generally supposed. The serious characters of the fracture of the surgical neck of the scapula is the ease with which it can be overlooked in the first instance because the accompanying symptoms do not alarm the patient at the time of the accident or induce him to seek medical advice and also because when examined owing to the position of the neck of the scapula difficult of access even from the axilla the lesion may be overlooked entirely or be mistaken for simple contusion of the shoulder. The diagnosis should always be confirmed by radiogram. Maglillo finds that this fracture is caused more frequently by indirect violence such as falls on the palm of the hand than by direct violence, in the proportion of three to one. It is not possible to speak of a typical line of fracture because the effect of the injury is modified by variations of the coverings of the joint and the resistance of the ligaments of the scapulo-humeral girdle. In most cases the essential cause of the fracture is the rebound from below upwards of the head of the humerus against the articular surface of the glenoid to which is added the force of gravity of the body weight. Care usually results in the condition is not complicated by lesions of vessels or nerves, and if treatment consisting in a supporting bandage followed by massage and passive movement is adopted in good time.

### 6. Herniotomy and Appendicectomy

K. MERRINGAS (*Zentralbl. f. Chir.* May 21st 1927 p 1282) while admitting that the suggestion has no merit in general approval recommends that when a radical cure for a right inguinal hernia is to be performed the supra inguinal method should be selected in order that the appendix may be excised and removed as a prophylactic measure before the performance of Bassini's or another radical operation. Merringas has employed this as a routine operation in all cases of right oblique inguinal hernia of which he has operated during the last seven years. He concludes that such opportunely appendicectomy is indicated in all cases, and can be performed easily. He adds that when an interval appendicectomy is performed the internal inguinal ring should be closed in order to prevent the subsequent occurrence of an oblique inguinal hernia.

7 Treatment of Ulcers Associated with Crural  
Phlebitis

R LEPICHE (*Bull et Mem Soc Nat de Chir*, April 15th, 1927, p 561) draws attention to the possibility of improving or even curing the complications associated with phlebitis of the lower limbs. He records the case of a woman, aged 29, who for two years had suffered from deep ulcers of the left leg following phlebitis. The ulcers had resisted all kinds of treatment, including antisyphilitic. At a subsequent laparotomy Lerloche found the left Fallopian tube fixed by dense adhesions to the left pelvic wall. The peritoneum was much thickened and dense inflammatory tissue covered the left external iliac vessels. The vessels were dissected out and freed from this tissue. Four days later the ulcers showed definite signs of healing, their surfaces were clean, sterile, and healthy looking. Skin grafts were then applied and on the seventeenth day the ulcers had healed. Lerloche thinks that his success in this case holds out a hope of relieving this troublesome condition where it follows pelvic inflammation, and adds that it is not unlikely that many cases regarded as incurable are due to this same cause, and could be improved by a similar method of treatment.

## 8 Papillomatous Tumours of the Breast

D HART (*Archives of Surgery*, April, 1927, p 793) reports the result of investigating a series of papillomatous tumours of the breast, of which 104 were benign and 24 malignant, in 5 the nature of the growth was uncertain. The points in differential diagnosis are emphasized, and it is added that in many cases are as cancer. In the benign group haemorrhage in the nipple was present in 66 per cent, sometimes in the absence of any palpable tumour. In the absence of other symptoms discharge is not always an indication for operation. Benign tumours were found at any age after puberty, malignant only after 35 years of age. The benign type is rarely found in the male breast, and may have been present for many, even twenty years. These tumours have a firm nodular consistency due to the presence of cysts filled with fluid, and are usually found in the centre of the breast. The skin is normal over the tumour, but there may be retraction of the nipple, the cysts contain papillomata, but there is no invasion of the wall. Tumours of the malignant group were typical of cancer in many cases. The cancer may arise in a cyst or in the breast whole cysts are present. The tumour was usually large, pain was present in 67 per cent of the malignant cases and 41 per cent of the benign. In doubtful cases Hart states that the tumour should first be excised and then thoroughly examined rather than explored. Removal of the breast alone is unjustifiable, being an inadequate operation for cancer and excessive for benign tumour. In the benign group 65 per cent of the patients were followed up and none developed cancer. The malignant tumour was found to be of a high grade of malignancy, and a large percentage of the patients operated on died of recurrence. This is offered as a further proof of the correctness of the division into two groups.

## Therapeutics.

## 9 A Mercurial Diuretic (440-B)

MOUQUIN, R. GIROUX, and S. SCHMIDT (*Paris Med*, May 14th, 1927, p 457) describe a diuretic obtained by the addition of mercuric acetate to ethyl allyl amido acetic acid in a watery medium, it is termed 440-B. Marked diuresis was produced by this preparation within a few hours. Intramuscular administration is recommended in preference to the intravenous method. The doses ranged from 0.5 to 2 c.c., and it is thought that they should vary according to the weight of the patient. The authors suggest one injection a week, and add that the dose must not be given more frequently than every four days. They state that in grave cachexias, serious cardiac and hepatic insufficiency, even with signs of collapse, the injections have no effect, and in cases of fever, even though slight, the drug seems to be contraindicated, but it has been used with success in cases of nephritis, hypertension, obesity with oedema, serous pleurisy, cardiac insufficiency with oedema, and chronic hepatitis with oedema. Its mode of action is probably not directly upon the kidneys. In no case did albuminuria or haematuria follow the injections, no crystals were passed, and there was no increase in the urea content of the blood.

10 P. CARNOT, B. BARTY, and B. BORTANSEI (*Paris Med*, May 14th, 1927, p 463) have treated cases of cirrhosis with 440-B prepared in the Pasteur Institute. They state that this preparation can be administered intramuscularly as a 1 c.c. dose. One injection provokes a polyuria, reaching its maximum during the ensuing twenty-four hours. In severe cases, and will not be

able and typical cases a secondary smaller polymia occurs a few days later. Charts are given to show the resulting increased amounts of urine in cases of alcoholic cirrhosis with ascites and hydrothorax, alcoholic cirrhosis with oliguria and marked hepatic insufficiency, cardiac insufficiency of the hepatic type, and anaemia. The authors observe as a result of treatment: (1) A great increase in the amount of urine passed during the first twenty-four hours—as much as 2 to 4 litres—followed by a fall to the previous subnormal level on the next day. Three to ten days later a second, though smaller, increase occurs. The action is said to be less intense in advanced cases of hepatic insufficiency, and the diuresis is proportional to the amount of fluid and chlorides in the tissues. (2) An increased elimination of chlorides parallel with the elimination of fluid. (3) Diminished urea concentration in the urine, but nearly always a slight increase in the total amount of urine passed. (4) The drying up of serous effusion such as hydrothorax. The authors mention the similar action of calomel and mercuric cyanide, which, they state, are less effective and constant than 440-B.

## 11 Parathyroid Extract in Haemorrhage

B. GORDON and A. CANTAROW (*Journ Amer Med Assoc*, April 23rd, 1927, p 1301) administered parathyroid extract in 347 cases of haemorrhage from such various sources as the respiratory, gastro-intestinal, and genito-urinary systems, operative incisions, and in jaundice and other conditions in which the clotting time of the blood was prolonged. The best results followed one to three subcutaneous injections of from 10 to 15 units at intervals of thirty-six hours; these were continued until the haemorrhage ceased, after which a final dose was given thirty-six hours later. Other treatment was stopped as far as possible during the investigation. Cessation of haemorrhage occurred in 304 patients following one or more transient increases in the calcium content of the blood. When the treatment was tested as a pre-operative measure in jaundice it was found that the coagulation time was reduced to within normal limits and haemorrhage was apparently prevented. The authors state that overdosage or prolonged administration in patients who do not respond may lead to unfavorable results, which may also occur in blood dyscrasias (puerperal haemorrhage and haemorrhagic disease of the newborn) irrespective of the size and number of the doses, apparently owing to local changes in the tissues. Insufficient time to permit a maximum hormone effect may also lead to failure, since increase of the blood calcium and a lowered coagulation time do not occur until three hours after an injection. The method was found valuable in patients recovering from operations when oral therapy was impossible. As compared with the oral and intravenous administration of calcium the injections of parathyroid extract gave more dependable results, they afforded a means of effectively mobilizing the calcium salt normally stored in the body, which is necessary for clotting.

## 12 Preoperative Iodine Therapy in Toxic Goitre

A. GRAHAM (*Inner Journ Surg*, May, 1927, p 354) discusses the use of iodine as a preliminary to operation in cases of toxic goitre. Iodine is given not to cure disease, but to improve the patient's condition for operation. The one indication for the administration of iodine is the presence of active hypertrophy and hyperplasia of the thyroid gland. The most striking improvement occurs in patients who have had no iodine previously, they invariably improve when given Engel's solution, as shown by decrease in the nervousness, flushing, palpitation, and tachycardia, and a corresponding fall in the basal metabolic rate. The thyroid gland itself becomes firmer and may become in time quite hard. This is the result of the storage of iodine and colloid material in the gland. The greatest advantages occur when the thyroid is convoluted to the colloid state by large doses of iodine in a comparatively short period of time. With adequate preparation a subtotal thyroidectomy is a safe procedure in most instances. Patients who have had iodine previously show the greatest variations in their response to its use as a preparation for operation. The previous use of iodine over prolonged periods deprives patients of this valuable aid in preparing them for operation. Even though the response in such cases may not be so favourable it appears a safe procedure to resume the iodine before performing the thyroidectomy. The presence of adenomas in the gland is not a contra-indication to the use of iodine.

## 13 Sanocrysin in Pulmonary Tuberculosis

K. PUR and H. POHL (*Med Klinik*, May 6th, 1927, p 673) report the results of treating patients with pulmonary tuberculosis by sanocrysin. In every case records of the physical signs were made directly and by x-rays blood films were examined the sputum rates of the blood cells were determined temperature charts and weights were kept, and the patients were followed up. Extension has been very materially reduced to about £12,000.

amount and bacteriological contents of the sputum were noted. In febrile cases the authors commenced with doses of 0.05 to 0.1 gram and slowly raised this at weekly intervals, in two cases they commenced with 0.25 gram and quickly increased the dose to 0.35 and 0.5 gram. Of the eleven patients under observation three were improved, one remained unchanged, three became worse and four died. In the cases which benefited there was, in a relatively short time, an almost complete disappearance of the exudative signs in the lungs, a condition which must certainly have resulted from the injections of sacrocrystin, in one of the cases the x-ray picture showed marked improvement clearing throughout the lungs and diminution of the cavities to half their size. On the other hand in patients who became worse or died there was no retardation of the rapid progress of the exudative processes such as that credited by the Danish authors nor was the statement confirmed that after several injections of sacrocrystin the tubercle bacilli disappeared from the sputum. In one of the patients who improved a vivid scarlatiniform rash developed on the body and face accompanied by pain and oedema of the feet, after dequamation the fresh skin showed numerous painful pustules the size of rice grains. The authors regard this exanthem not as the effect of a tuberculous endotoxin set free by the desintegrative action of sacrocrystin but as an undesirable effect of the heavy metal on the tuberculous patient.

## Laryngology and Otology.

### 14. Endocrine Deficiency as a Cause of Disease of the Ear

D. W. DRAKE (*Journal Laryngol and Otol* June 1927 p 375) reports two cases in which tinnitus vertigo and a more or less marked sense of fatigue yielded to thyroid medication and suggests that the possibility of endocrine hypofunction as a cause of ear diseases should not be overlooked in auricular practice. In another case a woman with obstruction of the Eustachian tubes and thickening of the mucous membrane of the sinuses, the administration of thyroid extract was followed by definite benefit and an associated inability to respiratory infections was removed. A fourth patient a man complaining of intermittent deafness, excess of tinnitus, arthritis and neurasthenia was similarly much improved by thyroid medication and a fifth patient a married woman, aged 30 with defective hearing, and deafness of the auditory canal, became much better after local treatment had been reinforced by the administration of thyroid extract. The author mentions also a series of pituitary cases in which treatment on similar lines proved effective. He adds that endocrine medication must not be regarded as a panacea though latent forms of thyroid hypofunction are probably more common than is generally recognized.

### 15. The Diagnostic and Therapeutic Value of Bronchoscopy

A. A. HALLIDAY (*Canadian Med Assoc Journal* May 1927 p 561) discusses the bronchoscopic method of diagnosis and treatment of certain disorders of the throat and lungs and emphasizes the importance of co-operation between the physician and radiologist. Its indiscriminate use is condemned and Halliday states that the method should only be employed after thorough preparation and careful physical and radiological examination of the chest. From the experience of about a hundred bronchoscopies in which Jackson's tubes and technique were used Halliday concludes that a certain percentage of lung suppuration cases can be cured by bronchoscope drainage, a large percentage improved and relief from distress given to most while drainage and treatment relieve a certain percentage of asthmatics especially those with a tracheo-bronchitis. An hour before treatment 1/4 gram of morphine is given hypodermically or a tablet containing hyoscine 1/100 gram morphine 1/4 gram and lactine 1.60 gram and in patients over 16 years of age a 10 per cent solution of cocaine is applied to the pharynx sufficiently far down to inhibit the function of the superior laryngeal nerve. After the second or third treatment the hypodermic is omitted. No general anaesthetic is given. Each treatment lasts about five minutes. Contraindications include laryngeal tuberculosis, recent profuse haemorrhage, organic disease of the heart and great blood vessels and disease of lung tissue involving one half or more of one lung. The treatment may be said to be indicated when it is desired to supplement general measures by improved drainage. For diagnostic lung mapping with lipiodol the method not only permits inspection of the air passages and aspiration of secretion but it allows of accurate instillation of the solution into any part of the tracheo-bronchial tree and its removal if necessary afterwards. By this means it is possible to out-

line abscess cavities, the degree and extent of bronchiectasis, the demonstration of structure, and the localization of foreign bodies.

### 16. Laryngeal Complications of Influenza.

E. J. MOLPE (*Journal de Med de Bordeaux*, May 10th, 1927, p 339) classifies these under the following heads: catarrhal, ulcerous infiltrating spasmodic and perichondritis. The catarrhal complications resemble an ordinary acute laryngitis, but usually last longer and are often accompanied by muscular weakness of the cords. In the ulcerous forms symmetrical erosions very resistant to treatment appear on the anterior third of the vocal cords. The infiltrating type is said to be the most characteristic of influenza. In these cases there may be few symptoms during the daytime, but towards evening troublesome cough and irritation set in and may go on to laryngeal stenosis and difficulty of respiration. These nocturnal exacerbations are very characteristic. On examining with the laryngoscope oedema of the posterior part of the arytenoid region can be seen. The spasmodic form is most likely to appear during convalescence, starting with troublesome tickling in the throat and going on to frequent spasmodic cough without secretion. Perichondritis is uncommon but may occur either in a mild form or as a very severe and often fatal affection the author refers to one such case where it ended fatally. Brief accounts are given of the treatment suitable for these various types of post-influenzal laryngitis. It includes no applications to the throat in infiltration of powders containing antipyrine, adenosine or cocaine inhalations of menthol thymol and eucalyptol and the insertion into the no trills of pastes containing medicament. For internal administration he recommends quinine, aceto-salicylic acid, antipyrine, and belladonna.

### 17. Retrobulbar Neuritis caused by Ethmoidal Sinusitis

J. FLANN (*Med Journal of Australia*, April 9th 1927 p 573) reports a case of retrobulbar neuritis associated with sphenoidal and ethmoidal sinusitis in a man, aged 57 who had suffered from headache for two years over and behind the right eye and from post-nasal catarrh. His visual acuity with the right eye was nearly normal with glasses but he stated that he had never seen with his left eye which was amblyopic with a very high degree of myopic astigmatism. There was no fundal change. Six weeks before his sight became blurred and the neuralgic pain about the right eye increased, the eye was tender on pressure its movement was painful and there was a definite central scotoma for red and green. There was no history or sign of any other cause than sphenoidal or posterior ethmoidal tonsils. Submucous resection of the septum was performed and both middle turbinates were removed the posterior ethmoidal cells on both sides were curetted and the right sphenoidal orifice enlarged with forceps. No actual pus was detected but the ethmoidal were in a crumbly and juicy condition. Four days later he could read the top print on the charts and was having warm saline nasal douches, and a week later was discharged with normal vision. Three and a half months later he complained again of headache and pain behind the right eye of a week's duration, but the eyesight was normal and the nose clean. The application of trichloroacetic acid diluted 1 in 3 to the right sphenoid on three occasions relieved the condition and two years after the first attack he appeared to be normal. Flynn suggests that this sequel indicates that the retrobulbar neuritis was effectively dealt with by the sinus operation and emphasizes the necessity of clearing out the sinuses in such cases even though no pus is seen in the nasal cavities at the time of examination.

## Obstetrics and Gynaecology.

### 18. Treatment of Puerperal Eclampsia and Sepsis

C. A. F. HINGSTON and A. L. MCDONALD (*Indian Medical Association Journal*, April 1927 p 179) emphasize the importance of prophylactic measures during the puerperium with special reference to eclampsia and sepsis. They review 2,000 cases of eclampsia and agree that this condition occurs usually in primiparae, and nearly always in the second half of pregnancy. It is most frequent at term. A high blood pressure ranging usually between 160 and 170 mm was found to be the most important symptom. For prevention of the fits rectal or vaginal pressure is essential. During severe attacks under the anæsthetic recommended the administration subcutaneous of veratrine (1 ccum if the pressure is above and 1/2 ccum if it is below 140 mm). Morphine in 1 + 0.13 gram doses repeated at intervals of two to three hours may be administered. They think that a small dose of 1/2 gr. should not be less.

adopted, but the second stage of labour should be terminated quickly without waiting for signs of maternal or foetal distress. The prognosis is said to be more favourable in post than in ante partum eclampsia, and poorest in intra partum cases. Complications such as pneumonia, cardiac failure, and insanity are treated if they arise, but they should be prevented, and careful nursing is essential. In the case of puerperal sepsis (ibid., p. 182) the authors consider ante-natal care the most important form of prophylaxis. Vaginal examinations, only made when absolutely necessary, should be preceded by a scrupulous cleansing of the labia and perineum. They have abandoned high forceps operations as being likely to cause sepsis, and perform version and extraction instead. Post partum debris, such as membranes and blood clots, should be removed without intrauterine manipulation. If sepsis occurs diligent search must be made for the cause. In septicaemic cases hot antiseptic vaginal douches may be given every four hours, continuous irrigation being valuable when there is sloughing of the vaginal walls. The uterine douche and enema should not be employed, drainage with a Budin's tube being sufficient, but repeated swabbing with sterilized gauze has proved very useful. In cases of subinvolution the administration of ergot and quinine or pituitrin is recommended. Operative measures should be performed only when definitely indicated. Careful nursing, stimulating treatment, and a liquid diet are necessary adjuncts, and any complications should be immediately treated.

#### 19 Appendicitis and Pregnancy.

G. BARBARO (*These de Paris*, 1926, No. 653), who records an illustrative case with a review of the literature, concludes that the first attack of appendicitis is not more frequent during pregnancy than at other times, but the occurrence of a relapse is favoured, that appendicitis may be the cause of interruption of pregnancy, and all forms of appendicitis may be met with in pregnancy. Pus formation occurs earlier and more frequently during gestation than at other times, its incidence and mortality of appendicitis are higher in the pregnant than in the non pregnant woman, and the mortality is higher in cases in which no operation is performed than in those which submit to surgical intervention. The symptoms vary considerably and the difficulties of diagnosis increase with advance in pregnancy. Mild cases often escape examination and are attributed to the state of pregnancy only. Labour is very dangerous in appendicitis, relief occurs immediately after delivery, but is soon followed by a rapid aggravation of the symptoms, and the diagnosis is often very difficult in the puerperium. Surgical treatment is definitely indicated in every case of acute appendicitis, the operation should be performed as soon as possible during the attack and at an early stage of pregnancy. The operative technique is almost identical with that for appendicitis apart from pregnancy. Barbaro adds that it is advisable to remove the appendix from every woman who has had one or more attacks, in order to prevent the severe complications which may occur during pregnancy.

#### 20 Paget's Disease of the Vulva.

E. VAN DER HOOP, C. BONNE, and W. F. WASSINK (*Amer. J. Gynecol. & Obstet.*, April 9th, 1927, p. 1833) record the third case to be published of Paget's disease of the vulva. In a married woman, aged 43, the subject of psoriasis, an eczematoid eruption of the vulva had developed four years previously, it resembled Paget's disease of the nipple and was accompanied by much irritation. About four months before admission to hospital a growth appeared in the right labium minus which proved to be carcinoma. The vulva, including the clitoris, labia minora, and the skin of the labia majora, was excised and subsequent recovery was uneventful.

#### 21 Precancerous Change of the Cervical Epithelium.

O. V. FRANQUE (*Zentralbl. f. Gynak.*, April 9th, 1927, p. 898) and H. HINSELMANN (ibid., p. 901) refer to the importance of recognition of leucoplakia of the cervix uteri as a condition which, whether considered to be a pre-carcinomatous stage or a commencing carcinoma, demands speedy radical treatment. Leucoplakia in the cervix, described twenty years ago by von Franque, is a condition of which Hinselmann has only been able to find six reports in the literature, nevertheless Hinselmann, examining the cervix by his colposcope with magnification of three to fourteen times, has detected two cases among a series of 220 during nine months. The cervix was amputated in both these instances, and the histological findings, described and illustrated by von Franque, in the epithelium of the margins of the patches of leucoplakia, are regarded as justifying this treatment. Hinselmann believes that colposcopy is of great value in recognition of precancerous or early carcinomatous states of the cervix uteri.

## Pathology.

### 22. Serological Classification of Fusiform Bacilli.

P. L. VARNEY (*Journal of Bacteriology*, April, 1927, p. 275) has isolated eighteen strains of fusiform bacilli from the mouths of normal and diseased persons. The method he used was to streak 4 per cent human blood agar plates with the undiluted pus, sputa, or mucus, incubate them anaerobically for two days, and examine the colonies under a dissecting microscope. Single colonies were transplanted to fresh plates, and the process was repeated until pure cultures were obtained. Among the eighteen strains isolated there were four different morphological types: Type I, filamentous bacilli; Type II, of short wavy filamentous bacilli; Type III, of long wavy filamentous bacilli; and Type IV, of broad stubby bacilli, such as Vincent's spirillum, mixed together in the same culture, and have concluded that the bacilli and the spirilla were two forms of a single organism. According to Varney, however, this is undoubtedly erroneous, fusiform bacilli and spirilla are two entirely separate organisms, a mixture of the two occurring only in impure cultures. The spirillar forms of Type III are not likely to be confused with the spirilla. A serological study was then made of the different types. Antigens, both for immunization and for agglutination, were prepared by washing off forty-eight hour blood agar cultures with saline serum. Serums were prepared only against the first two types. The results showed that the eighteen strains could be divided into three main serological types by direct agglutination, Types I and II have each a subgroup. No antigen could be prepared for the broad stubby bacilli, but as these organisms differed morphologically from the others, they have been grouped as Type IV. The wavy bacilli failed to agglutinate with either Types I or II serums, and are therefore classed as Type III. The author concludes with a full morphological and cultural description of the organisms of the different types.

### 23 Calcification of the Kidney.

W. S. PUGH (*Urol. and Cut. Rev.*, April, 1927, p. 208), who records an illustrative case, states that occasional areas of punctate calcification are not uncommon in the kidney, though they may be so small as to be easily overlooked. Oppenheimer in 9.8 per cent of 347 necropsies recorded peripheral punctate calcification, one being found in over sixteen persons over 30 years of age, the youngest being 16 and the oldest 89. More than three-fourths of his cases occurred after the age of 50. Experimentally calcification is readily produced in the kidney by ligaturing the renal artery or the ureter. The deposit in such cases is usually in the form of calcium phosphate, while that produced by a disease process is usually calcium carbonate. A study of the literature shows that lime may be found in the kidney under the following conditions: (1) in the papillae in advanced age, (2) in resorptive processes of the skeleton, (3) in interventions such as those due to mercury and phosphorus, (4) in fibrous atrophied glomeruli, (5) in the renal pyramids in small pox, (6) in children with catarrhal enteritis and in scarlet fever, (7) in renal tuberculosis, (8) possibly as a post mortem change. Pugh's case occurred in a man, aged 34, who after five intravenous injections of 10 c.c. of a 1 per cent solution of mercuriochrome for chronic prostatitis, developed chills, fever, pain over the left kidney, and considerable salivation. X-rays showed calcification of the left kidney. The urine was apparently normal. Complete collapse and death supervened.

### 24 Etiology of Intestinal and Genital Tuberculosis.

J. TRIAS (*La Med. Ibera*, May 21st, 1927, p. 567) states that two forms of intestinal tuberculosis can be distinguished from the pathogenic standpoint. The first is found in the last stage of pulmonary tuberculosis, in which massive ingestion of tubercle bacilli is followed by their localization in the intestine and subsequent formation of intestinal lesions which are inoperable. The second form is of much greater theoretical interest, because the pathogenesis is not so clear as in the first form. It is also of greater practical interest, because it usually occurs in persons in whom the lesion is curable by surgical intervention. In the female sex transmission of tuberculous lesions of the adnexa to the intestine is possible by direct contiguity or by lymphatic channels, while in the male sex only the last route is available, the epididymis being the analogue of the Fallopian tube. Transmission by direct contiguity in the male sex is possible only in cases of the vesiculæ seminales, which are partly invested by peritoneum. In fourteen cases of intestinal tuberculosis recently studied by Trias lesions of the epididymis were found in seven. The genital lesion is not usually the first but the second stage in a cycle, of which the other stages are a preliminary one of pulmonary tuberculosis and a final one of intestinal involvement.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

### 25. Hypersensitiveness Following Injection of Toxin Antitoxin

W E GATEWOOD and C W BALDIDGE (*Jour. Am. Med. Assoc.* April 2nd 1927 p 1063) record six examples of marked tissue hypersensitiveness in adults who had previously been given toxin antitoxin, and on injection with diphtheria or scarlet fever antitoxin developed the phenomenon of Arthus which consists in local necrosis at the site of serum injection. A STEWART (*ibid.*, April 16th, 1927 p 1220) states that in a series of ten animals which had received a single injection of 1 c.c. of 0.1 L. toxin antitoxin and a second intraperitoneal injection of diphtheria antitoxin sixteen days later symptoms of non fatal anaphylaxis appeared in various degrees of severity and after different intervals. In a second series of three animals which had been given three injections of 1 c.c. each of toxin antitoxin prompt anaphylactic death occurred in two instances with convulsions and cessation of respiration while the third animal remained well. Stewart also reports the case of an infant previously immunized by three injections of 0.1 L. toxin antitoxin who developed a prompt serious reaction after an injection of 5 CCG units of antitoxin for diphtheria fourteen months later in spite of a small desensitizing dose twenty minutes previously. To avoid such anaphylactic reactions the authors advise the use of a preparation containing serum other than that of horses such as goat's serum which is recommended by Healer or the use of a toxin detoxified by sodium bicarbonate.

### 26. Hodgkin's Disease

S GINSBURG (*Arch. Int. Med.*, April 15th 1927 p 571) considers that Hodgkin's disease must no longer be regarded as a specific enlargement of the lymph glands and spleen with occasional deposits in other viscera associated with severe secondary anaemia. He maintains that it is a specific malignant general disease, with protean manifestations in which any tissue or organ may become clinically primary and predominantly affected. The condition is characterized by a specific hyperplasia of the reticulo endothelial elements the cellular proliferative stage being followed by necrosis and fibrosis, with increasing toxemia and anaemia as the disease advances. Ginsburg states that the nervous system may become clinically primarily, and predominantly affected and give rise to symptoms for months or years before there is any demonstrable enlargement of the lymph nodes or spleen. In thirty six cases of Hodgkin's disease observed between 1914 and 1925 invasion of the nervous system was recognized in ten cases or 27.7 per cent. He adds that diagnosis of involvement of the nervous system depends on thorough and complete study of all the clinical signs and symptoms, a neurological examination even if supplemented by laboratory tests, is insufficient. In doubtful cases the radiotherapeutic test may give considerable assistance since the lesions in Hodgkin's disease are very radio sensitive before the onset of extensive degenerative fibrotic changes. Quick subsidence of pressure phenomena may give a clue to the diagnosis and relieve an early paraplegia or brain lesion. Ginsburg considers radiotherapy the chief measure in treating this malignant disease, but adds that it must be used early, for it has no efficacy in old fibrotic stages.

### 27. Mumps in a Danish Island.

S ROHLER (*Ugeskrift for Læger*, April 14th 1927 p 294) describes an epidemic of mumps in a village on one of the Danish islands about thirty years after there had been any case of this disease in the district. The epidemic began in June 1925 and lasted till the beginning of October. It was introduced by a young fisherman who had been infected on board an English trawler and who became ill a few days after his return home. The evening before he fell ill he took part in a public dance with the result that two to three weeks later many new cases developed. The only preventive measures taken were to isolate the patients themselves and to keep the children of school age belonging to the infected families away from school as long as the affected glands were swollen. There were seventeen houses in the village occupied by forty persons under the age of 30 which remained totally immune. It would therefore seem that infection with mumps always depends on direct contact between persons and that this contact must be close. In fourteen other houses all the inhabitants under the age of 30 were attacked, they numbered 51. In nineteen other

houses most of the inhabitants under 30 were attacked but a few remained immune in spite of daily and intimate contact with one or more of the patients. Among the 390 inhabitants of the village there were 210 under the age of 30 living at home and of these 210 persons as many as 121 were attacked. The young men were more immune than the young women possibly because the latter remained more indoors and in closer contact with the patients but their natural immunity may also have been less. Only 4 persons over the age of 30 developed the disease. The author treated altogether 131 cases of which 74 were bilateral in most of these bilateral cases the swelling was greater on one side than on the other. In 53 cases the disease was unilateral or almost so—that is there was only a suspicion of a swelling on the other side. In 3 cases, both the parotid and the submaxillary glands were involved and in one case the submaxillary gland alone was swollen.

### 28. Spirochaetosis Icterohaemorrhagica

C C E BURGER (*Nederl. Tijdschr. Genees.* May 7th 1927 p 2450) alludes to the case recently recorded by I C Clijndert jun (*Lijp.*, March 12th 1927 part 270) and records a case in a soldier aged 19. Apart from vertigo and loss of consciousness, the patient did not appear to be ill and his complaint was at first mistaken for ordinary catarrhal jaundice. A fresh rise of temperature however with increase of the jaundice on the thirteenth day as well as the pre existing nephritis and complaints of vertigo and clamps in the calves suggested the possibility of Weil's disease which was confirmed by serological and bacteriological tests. Another feature of the case was the peculiar orange tint of the jaundice which appears to be more or less typical of the disease. The patient also had a morbilliform rash on the chest, abdomen and arms, the occurrence of which in spirochaetosis is mentioned by Miles. The patient was in Clevier's case probably contracted his infection in a contaminated bathing place.

## Surgery

### 29. Diagnosis of Gastric Carcinoma.

V C MACCARTHY (*Brit. Journ. Med. Sci.* April 1927 p 466) is the result of investigating 967 cases of gastric ulcer and 1353 of carcinoma reports that when multiple chronic ulcerations occur alone may be found to be carcinomatous. Chronic ulcers whether simple or malignant vary greatly in size those larger than 2.5 cm in diameter usually show carcinomatous change though this is less frequent in subacute perforating ulcers. The smallest gastric carcinomas have been seen in the borders of simple chronic ulcers not in the base when found in the base the malignant change is always in the border (mucosa). The reverse of this is not always the case. Studies of living and unfixed fresh cells of the gastric tubules in the borders of chronic ulcers reveal significant facts. In some ulcers the cells of the tubules are columnar (normal) with small spheroidal nuclei and inconspicuous nucleoli. In others these cells are replaced by ovoid or spherical cells with large nuclei and nucleoli which are morphologically indistinguishable from malignant cells. In such ulcers the cells are all apparently intratubular. Though this is not a carcinomatous picture MacCarthy considers it suspicious and states that wide removal is the safest procedure. He suggests that this appearance might easily be overlooked by pathologists who are not cytologists, and are acquainted only with post mortem or fixed and embedded tissues. In some chronic ulcers this condition is found associated with the presence of the cells on the side of the tubule in the submucosa and lymphatics. This is a true carcinoma. MacCarthy adds that the differential diagnosis by clinical examination between early carcinoma and simple gastric ulcer is impossible.

### 30. Bone Changes in Renal Rickets.

ACCORDING TO E P BROCKMAN (*Brit. Journ. Surg.* April 1927 p 634) the occurrence in children of chronic interstitial nephritis associated with bone changes resembling rickets has been noticed in recent years. In a recorded case all the organs were normal except the kidneys which were both excellent examples of the condition known as compensated cystic kidney. Histological examination showed the changes of chronic interstitial nephritis. It was found that in

"renal rickets" the shafts are straight and the deformities are due to separation and displacement of the epiphyses. Osteotomy is not to be advised in view of the risk of necrosis being caused by the anaesthesia, and also the deformities tend to recur. The renal marrow is replaced by fat and there is very little new bone formation. There is active bone absorption by osteoclasts, and replacement of the absorbed bone by fibrous tissue. It appears that the nephritis exists for a long time before the appearance of the deformities. The lower ends of the bones are involved first. It is suggested that the renal failure allows a toxic condition to arise which affects the cells in the region of the growing disc and also the red cells of the marrow. Another view is that the factor producing the nephritis may also subsequently cause the bone changes to occur. There is no evidence that the condition is due to an ascending infection of the ureters or that it is related to nutritional changes.

### 31 Gonorrhoeal Arthritis Treated by Operation

LEFVRE, COSTEDOT, and JONCHERES (*Journ de Med de Bordeaux et du Sud-Ouest*, April 10th, 1927, p. 285) report the successful treatment of a gonococcal infection of the knee by incision. A man, aged 30, bruised his left knee about three weeks after an attack of gonorrhoea, a few days later a painful swelling of the knee appeared, and also stiffness, pain, and swelling of the left shoulder. The knee became globular, the local temperature was raised, there was per articular thickening, with oedema, and very definite intra articular fluctuation. Arthrotomy by simple lateral parapatellar incision was performed and purulent fluid was removed. Neither irrigation nor drainage was employed. On the next day passive movements were begun in spite of the existence of severe pain. As on the ninth day there was slight retention of pus with fever, a wick and a small drainage tube were inserted. Injections of gonococcal vaccine were given. An abundant flow of serous fluid persisted for more than two months, but the arthritis of the shoulder subsided rapidly. The knee retained its globular form, with serious muscular atrophy, particularly of the quadriceps, but the range of movement became normal, although there was very considerable relaxation of the ligaments.

### 32 Surgical Treatment of Herpes Zoster

G. PIERI (*Arch Ital di Clin*, April, 1927, p. 545) records the case of a man, aged 63, who developed left thoracic herpes zoster, followed by persistent neuralgia, which was not relieved by any of the ordinary analgesics. The ganglion of the fourth intercostal nerve was resected, and was found to be the seat of a chronic inflammatory process characterized by an abundant infiltration, with plasma cells and lymphocytes distributed diffusely or in more or less circumscribed foci. The nerve elements (cells and fibres) were mostly destroyed. The nerve trunks in the immediate neighbourhood of the ganglion showed evidence of interstitial neuritis. The operation cured the neuralgia and there has been no return of pain or disturbance of any kind during the subsequent ten months. Pieri concludes that resection of a spinal ganglion is indicated in cases of obstinate neuralgia of the spinal nerves following herpes zoster, in preference to resection of the posterior roots, which is a more severe operation.

### 33 Echinococcus in Iceland

S. MATTHIASSEN (*Ugeskrift for Læger*, April 28th, 1927, p. 348) draws attention to the remarkable decline in the incidence of echinococcosis in Iceland during the last sixty years. From being the most infected country in the world in this respect Iceland is now outdistanced by Tunis, Morocco, and certain other countries bounding the Mediterranean. Sixty years ago it was calculated that 20 per 1,000 of the inhabitants of Iceland were infected. The estimate made of late years of an incidence of one case per 1,500 inhabitants is probably too high. Twenty-five years ago, in the author's hospital experience, echinococcus operations were the most common abdominal operations, whereas at the present time he performs such operations only three to five times a year. He attributes this improvement to the better standards of living and the increase in the number of doctors from eight, sixty years ago, to about ninety at the present time. The proportion of dogs to human beings has also greatly changed, in 1863 there was one dog to three to five persons. Legislation in 1869 and 1890 imposed a tax of 2 to 10 krona for every dog, and at the present time there is only one dog to every fifteen persons. It also obliged all persons concerned with the slaughter of animals to burn or bury echinococcus cysts and infected offal, and local authorities were authorized to issue regulations concerning courses of vermicidal treatment of dogs every autumn after the slaughtering season, and to see that these regulations were enforced.

## Therapeutics.

### 34 Stovarsol in Malaria

M. FREIMAN (*Journ Trop Med and Hygiene*, May 16th, 1927, p. 127) describes the results of treating ninety-three cases of malaria with stovarsol, which is acetyl amino oxyphenyl isonic acid. The drug was given by the mouth in tablets containing 4 grains of active substance, the doses for infants under 1 year being half to one tablet daily, for children 1 to 6 years old, one to two tablets daily, from 6 to 10 years, three tablets daily, and over 10 years old, four tablets daily. Toxic symptoms were only observed in one patient—an adult. In acute cases the preparation was given in full doses until the blood test was negative, and continued uninterruptedly in half doses for three weeks. In chronic cases it was given in courses with intervals of ten days between each course. Forty-five patients with benign tertian malaria responded well, they were considered cured when free from parasites and clinical symptoms for three months. In four cases of pregnancy stovarsol was well tolerated, and it was found effective in cases refractory to quinine. No action was observed on parasites or symptoms in twenty cases of quartan malaria and in five of subtertian. Freiman concludes that this preparation has a specific action on *Plasmodium vivax*, but is ineffective when the infection is due to *Plasmodium malariae* or *falciparum*.

35 F. GUERIN, E. BORTL, and M. ADYER (*Bull Soc Path Exot*, April, 1927, p. 331) have attempted to estimate the value of stovarsol in the treatment of the various types of malaria. They tried to give effect to Sinton's rules for testing the efficacy of any treatment, but found that some of these could not be complied with in the conditions under which they worked. Sodium stovarsol was used, 1 gram being given intravenously in 8 c.c. of the vehicle. Temperature and blood observations were made during the following three days. The authors conclude that stovarsol has no direct action in malaria except in infections with *Plasmodium vivax*, that even in such cases, although all parasites may disappear temporarily from the blood, relapse within two months is the rule, and that in benign tertian cases stovarsol causes a febrile reaction not produced in the other infections. They agree, however, that stovarsol is a valuable adjunct to quinine in quartan and subtertian cases, and consider it a very effective remedy in benign malaria, although not a definitely emetive drug.

### 36 Manganese in the Treatment of Pulmonary Tuberculosis

O. HELMS and J. FREDERIKSEN (*Ugeskrift for Læger*, May 5th, 1927, p. 371) started in the summer of 1924, at the Nakke hofsfjord Sanatorium in Denmark, intravenous injections of minute doses of manganese. This treatment was based on the experimental work of Walbum, who found that the injection of small quantities of metallic salts stimulated the tissues of animals to produce antibodies. By November 1st, 1926, 115 patients had completed courses of manganese treatment, and 97 had been discharged. Only 42 were in the first stage of the disease, 27 being in the second, and 46 in the third stage. Of the other sanatorium patients who were discharged without having had this treatment only 48 per cent were in the second and third stages of the disease. Thus the manganese treated patients were on the whole more ill than the others. The injections were usually given twice a week, and in most cases each patient received from twenty to thirty. There was little or no reaction, and in no case were alarming symptoms provoked. On the completion of the treatment 70 patients were improved, 43 were unaffected by it, and 2 were worse. The average duration of the treatment was sixty-seven days. Before the treatment 87 patients coughed up sputum, at the end of the treatment only 47 patients did so. In 15 other cases there was an appreciable reduction of the sputum, the amount of which was unchanged in 31 cases. Only in one case did the sputum increase during the treatment. Of the 115 patients, 27 had tubercle bacilli in the sputum before admission to the sanatorium, but not while in it, 69 were found to have tubercle bacilli while in the sanatorium. Thus there were altogether 95 who had, or had had, tubercle bacilli in the sputum. Of the 69, as many as 39 were sputum negative at the end of the treatment. Whereas tubercle bacilli occur in some cases in the sputum after they have been temporarily banished by stovarsol, this phenomenon is very rare in patients treated by manganese, and the authors conclude that this treatment is not only conservative, but is capable of rendering sputum negative in a greater proportion of patients than any other methods of treatment.

**37. Intracardiac Injections of Adrenaline.**  
H. HARTMANN (*Bull et Mem. Soc. Nat. de Chir.*, May 14, 1927, p. 625) draws attention to the value of injecting adrenaline into the heart when the beat has recently ceased, and reports three cases observed by J. Delaguerre. In the first, a man, aged 49, after being anaesthetized with ethyl chloride for an operation for anal fistula ceased to breathe, and the heart beat could not be detected. Artificial respiration was unsuccessful, but after about five or six minutes 1 c.c. of 1 in 1,000 solution of adrenaline was injected into the heart and was quickly followed by return of the pulse and natural respiration. Similar success followed the use of adrenaline in a case of heart failure during appendicectomy, but it failed in an eclamptic patient presumably owing to her toxic condition. Hartmann reports a successful case of his own and, by way of contrast, describes five cases in which the procedure failed to restore life. He believes that it is essential in such emergencies to combine artificial respiration and rhythmical traction of the tongue with intracardiac injections of adrenaline.

**38. Salvarsan in Quiescent Syphilis.**  
E. L. GLYNN, R. E. ROBERTS, and PHOEBE M. BIGLAND (*Brit. Jour. Ven. Dis.*, April, 1927, p. 83) as the results of investigations extending over a period of five years emphasize the value of prompt treatment of active syphilis by salvarsan and mercury, and add that the use of mercury alone is unsatisfactory, even when the Wassermann reaction is negative. Mercury seemed to increase rather than diminish the possibility of the return of a positive reaction. They add that such a Wassermann relapse signifies renewed spirochaetal activity, since salvarsan is a more potent spirochaetocide than mercury, extra courses of the former will prove more successful than mercury in preventing Wassermann relapses and in destroying any residual spirochaetes. The value of mercury in clinically active syphilis is admitted and it is only its value in quiescent syphilis when the Wassermann reaction is negative that is criticized. Mercury is admittedly a cumulative poison and may depress the patient's immunity.

## Anaesthetics.

**39. Novocain Analgesia for Amputation of the Breast.**  
I. A. ANDREJEV (*Deut. Zeit. f. Chir.*, April 1927, p. 349) states that the employment of local anaesthesia and its indications have been considerably extended during the last few years. Thus in Schaeck's clinic 78 per cent of all operations are successfully performed by this method. Recently a number of surgeons such as Chaput, Hirschel, Brann, Meyer, Lberle and Kran have successfully used local anaesthesia for radical operation of the breast for carcinoma. Andrejev now records twelve cases of mammary cancer in women aged from 25 to 76 in whom the radical operation was performed under local anaesthesia at the surgical clinic of the Leningrad faculty of medicine. The indications for local anaesthesia were advanced age, cachexia, changes in the vessels, heart, liver, kidneys, diabetes and pregnancy. The term 'radical operation' includes amputation of the breast with removal of the pectoralis major and minor, clearing out of the axilla as well as the lymph glands of the infraclavicular region and, if necessary, the supraclavicular region as well. The local anaesthesia required is obtained in the following three stages: (1) Anaesthesia of the brachial plexus according to Kulenkampf's method with 20 c.c. of a 2 per cent solution or 30 to 40 c.c. of a 1 per cent solution of novocain. (2) Intercostal anaesthesia of the upper six intercostal nerves with 15 c.c. of 1/2 per cent solution of novocain. (3) Injection of the medial portion of the operation field with 1/2 per cent novocain-adrenaline solution. Andrejev never found it necessary to exceed a total amount of 300 c.c. of a 1/2 per cent solution of novocain. No complications of any kind were observed either during or after the operation. The time required to produce the anaesthesia ranged from ten to fifteen minutes. Almost all Andrejev's patients had enlarged glands in the axilla and subclavicular region and there was recurrence in two cases. As a rule the operation was quite painless; only two complained of pain while the axilla was being cleared out and required ether. The post-operative course was uneventful, although four of the patients were over 60.

**40. Intratracheal Administration of Ether.**  
F. W. GREEN (*Med. Jour. of Australia*, April 23rd 1927, p. 398) has for five years used as a routine the intratracheal method of administering ether and finds it of particular value in operations in which there is danger of blood or mucus entering the air passages. In tracheotomies operations it provides a positive lung pressure, and in operations such as

laminectomy, and nephrectomy, the postural difficulties are overcome. The method eliminates any local respiratory obstruction from spasm or congestion of the tongue, pharynx, or upper air passages. Green finds that the tendency to vomiting is much diminished and that there is a lesser liability to pulmonary complications, which in his last 600 cases, occurred in only 0.5 per cent. He describes the technique of administration and mentions that he gives 10 grains of chloroform on the previous night and another dose one hour before the operation together with 1/150 gram of atropine. The use of warmed ether is said to be essential, and care must be taken not to overfill the receiver. Green adds that quiet respiratory movements should accompany the anaesthesia after induction and the patient's face should retain a pink color. The appearance of cyanosis indicates that the ether has been too large or has not been passed far enough into the trachea.

**41. Gastric Dilatation during General Anaesthesia.**  
W. A. McIVER (*Annals of Surgery*, May 1927, p. 704) discusses the occurrence of acute dilatation of the stomach during the administration of a general anaesthetic such as ether and reports experiments which indicate that the gas concerned is atmospheric air. He produced such acute dilatation experimentally in animals and attributes its appearance to negative pressure in the thorax, the air being forced downwards into the stomach, which acts as a reservoir since its muscle tone is lowered by etherization. Oesophageal peristalsis is also believed to play an important part. He reports the case of a man, aged 23, in whom gastric dilatation occurred during an operation for acute perforation of a duodenal ulcer and refers to other examples in the literature. He adds that the immediate systemic effects of dilatation are slight, though the later effects in neglected cases may be serious. He attributes many of the symptoms to severe dehydration of the tissues.

**42. Spinal Anaesthesia and Intestinal Motility.**  
F. D. ALSTON (*Rev. med. de Barcelonn.*, March 1927, p. 227) records eighteen illustrative cases, in patients aged from 17 to 79, whom he classifies in the following three groups: (1) ordinary cases in which the intestinal motility had not been affected; (2) cases of dynamic ileus; (3) cases of mechanical ileus. His conclusions are as follows: (1) Spinal anaesthesia gives rise to an immediate increase of intestinal peristalsis which is very intense and persists for a long time. (2) Intestinal motility which is increased by spinal anaesthesia is inhibited by atropine under the influence of which the intestine returns to a complete state of rest. (3) Intestinal motility is also inhibited by inhalation of chloroform, the action of which persists only during deep anaesthesia. (4) The increase of intestinal motility produced by spinal anaesthesia is due to a temporary blocking of the preganglionic fibres of the splanchnic by the anaesthetic which becomes diffused into the subarachnoid space. (5) A proof of this action of spinal anaesthesia on intestinal motility is furnished by the section of the splanchnic nerves when the results are similar to those obtained by spinal anaesthesia. (6) In ordinary cases neither vomit nor post-operative paralysis of the intestine occurs. In dynamic ileus it puts an end to the symptoms, especially when peritonitis is present in mechanical ileus, though it is not able to remove the mechanical obstruction, as soon as this has been effected by surgical means the retained intestinal content are rapidly expelled. (7) The effects of spinal anaesthesia on intestinal motility are superior to all other methods as regards intensity, duration, and effect.

## Obstetrics and Gynaecology.

**43. Tubal Insufflation.**  
As the result of comparative observation of 112 cases of sterility and a number of normal confinements R. A. TSCHERTOK (*Zentralbl. f. Gynäk.*, April 16th 1927, p. 395) concludes that insufflation of the Fallopian tubes first described by Rubin in 1920 is a very reliable method of diagnosing patency of the tubes. He suggests that it might also be valuable occasionally in distinguishing a tubal swelling from an ovarian tumour or a subserous fibroid. His insufflation results were confirmed in 20 out of 21 patients who subsequently came to laparotomy. In one of the other cases the tubes were found impervious six days after insufflation but patent ten days later. In unsuitable patients such as those with cervical discharge, haemorrhage or fibroids are avoided and a careful technique is adopted, anaesthesia is not required and the risk of most of the complications mentioned in the literature is practically eliminated. Tschertok found that the so-called characteristic sound of gas escaping into the peritoneal cavity from the

umbilical ostium, audible in the iliac fossa, may be produced at the internal end of an occluded hydrotome. He considers the subjective sensations of the patient and the alteration in resistance of the rubber injection bulb palpable by the observer as hard to be unchangeable guides. He therefore connects a Woulfe's bottle with the tubing of the apparatus and injects air till the manometer reading is 80 mm. After this he continues more slowly, never exceeding a pressure of 180 mm., until bubbles appear in the Woulfe's bottle, this coincides with the escape of air into the peritoneal cavity. As the value of the test depends on occlusion of the whole cervical canal, and not merely of the external os, Tschertok uses a hollow dilator with a conical end measuring 3 mm. in diameter at the tip, 6 mm. at the base, and 2½ cm. in length. It has a stem of uniform thickness, which is bent at an obtuse angle to correspond with the junction of the cavity of the uterus with the cervical canal. If air is escaping through the external os during insufflation a hissing sound is produced. The author emphasizes the importance of uniform technique when comparing the statistics of primary and secondary sterility obtained by different workers.

#### 44 Heart Disease and Pregnancy

L. E. HAMILTON and F. S. KELLOGG (*Inner Journ Obstet and Gynecol.*, April, 1927, p. 535) discuss the obstetric management of cardiac patients, based upon observations in 822 cases in hospital and private practice. The great majority of patients with significant cardiac lesions complicating pregnancy have rheumatic heart disease with mitral stenosis and/or aortic regurgitation, during pregnancy there should be careful co-operation between the physician and the obstetrician. Early termination of pregnancy is advised when there are clear signs of congestive heart failure, a complicating nephritis, hypotension, auricular fibrillation, or a recent attack of rheumatic fever. Should decompensation occur during pregnancy the patient requires treatment in hospital until the pregnancy is terminated. Such a condition arising in cardiac patients previously not disabled is due to non observance of rules as to rest, to unforeseen intercurrent disease, and occasionally to some sudden cardiac complication such as auricular fibrillation. If operative measures become necessary the authors advocate ether anaesthesia by the open method as the anaesthetic of choice as being preferable to scopolamine, morphine, and local anaesthesia, because it is safer, it enables a Caesarean section to be performed more rapidly, and it obviates the danger of having to change over to a general anaesthetic in cases where twilight sleep excites the patient and renders her more liable to acute cardiac failure. They also consider it safer for the majority of multiparous patients with heart disease to be delivered by forceps at full dilatation, with sterilization if necessary some months later, than for a Caesarean section, with its added risk, to be performed for the sake of sterilization. They add that every obstetric hospital should have a cardiac clinic since it is only by accumulation of clinical data that the problems of heart disease complicating pregnancy can be solved.

#### 45 The Use of Iodized Oil in Gynaecology

I. B. STRIN and R. A. ARNS (*Radiology*, June, 1927, p. 494) recommend the use of iodized oil in gynaecological conditions when diagnosis can be facilitated by radiography. The uterine and tubal lumina can be clearly depicted thus, and the site of tubal obstruction sharply defined. This method of examination is said to be of less value when the internal wall is diseased, since the general contour of the organ, rather than its lumen, is altered, it is also of little or no value in the diagnosis of ovarian disease. Transuterine insufflation of carbon dioxide is described as a safe and useful procedure in gynaecology. Neither method is advocated for routine use, but only in selected cases, a combination of the two methods is said, however, to yield more information about the pelvic organs than any procedure other than intraperitoneal exploration.

## Pathology.

#### 46 Sensory Innervation of the Peritoneum and Appendix

M. DE VINCENTIS (*Il Polichino*, Sez. Prat., May 9th, 1927, p. 671), from observations during operation on cases of acute appendicitis and inguinal hernia, under spinal anaesthesia, the injections being between the twelfth dorsal and first lumbar vertebrae, reports that pinching the parietal peritoneum at the margin of the incision caused immediate pain in the back, followed by itching or burning sensation, stretching the appendix with the fingers caused no pain, but pulling on the mesentery of the appendix caused localized pain in the epigastrium. Cutting out the appendix which was swollen and vascular caused no pain. In operating on

hernia pain referred to the region of the stomach followed the stretching of the hernial sac, and also after each ligature of the omentum, but the other stages of the operation were not attended with pain. From this it appears that the painful sensations are conveyed by the large and small splanchnic nerves—that is, through the sympathetic system. The author concludes that the parietal peritoneum and the mesenteries are provided with sensitive nerve fibres derived from the sympathetic, which receives painful sensations only as the result of tension. He thinks it probable that many pains provoked in the intestines and appendix as the result of inflammation or functional disturbances depend on a mechanical lesion of the ligature of the omentum.

As pain, the pain of strangulated hernia should be regarded as arising from strangulation of the omentum. Epigastric pain, so common in diseases of the intestines and appendix, is stated to be a referred visceral sensation and derived neither from the coeliac ganglion nor from the solar plexus.

#### 47 Estimation of the Gastric and Intestinal Functions

J. BUCKSTEIN (*Med Journ and Record*, May, 1927, p. 610) advocates the use of a celluloid capsule for investigation of peptic activity and acidity, of the intra intestinal digestive function, and of gastro intestinal motility. A small piece of Congo red paper is placed within a perforated celluloid capsule. The capsule, attached to a silk string, is swallowed for a distance of 24 inches from the tooth, and after being left in the stomach for some minutes is withdrawn. The presence of free hydrochloric acid will be indicated by the paper becoming blue. The peptic activity of the gastric secretion can be studied by introducing a small Mott tube within the capsule, which is swallowed at night and removed the following morning before breakfast. For the determination of lipase an Einhorn capillary tube is placed within the capsule, swallowed at night for a distance of 36 inches from the teeth, and removed the following morning. In the presence of lipolytic digestion there is a change in the colour of the Nile blue sulphate contained in the capillary tube. The efficiency of intestinal digestion is tested in the following manner: small pieces of meat fibre, mutton fat, and potato are placed within the perforated celluloid capsule, which is then swallowed and removed as in the previous investigation. A marked resistance to digestion of any one of the three substances might be an indication for the diminution of that type of foodstuff from the dietary. Again, a small amount of bromum may be placed within the capsule, which is then sealed and swallowed. The course of the capsule as it traverses the entire canal may be followed radiographically, and the total time required for passing through the intestinal tract can be observed.

#### 48 Treatment of Rat Sarcoma with Antiserums

E. HARDE and P. HILNPI (*C. R. Soc. de Biologie*, May 20th, 1927, p. 1277) state that they have been able to confirm Lumsden's results on the antiserum method of treatment of tumours in rats. Altogether 38 rats were treated with serum, 19 rats served as controls. The best results were obtained by treatment with fresh serum, serum which had been kept in the ice chest for two or three weeks were apparently inactive. Thus 11 rats with a tumour on the flank were treated with fresh serum, and 8 of them were either cured or very much improved, on the other hand, 5 rats with similar tumours were injected with serum that was two or three weeks old, none of them was cured, though in 2 an inhibitory action was noticed. Again, 6 out of 9 rats with tumours of the paws were cured after the injection of fresh serum, whereas of 3 rats treated with the older serum 1 of one was improved. The authors consider that the beneficial action of the serum is therefore due largely to the lytic effect contained in it. They found that if in a rat suffering from a tumour on each of its hind paws the serum injection was made on one side only, the disappearance of the tumour on the treated side was often, though not invariably, followed by disappearance of the tumour on the other side. However, held good only with tumours on the paws, rats with tumours on the flank this was not observed. The results were obtained with an anti Jensen rat sarcoma serum. The action of an anti embryonic serum was then tested. It was prepared by the injection of embryonic tissue of a horse or fowl into rabbits. *In vitro* this serum had a marked lytic action towards tumour cells, in *vivo* the lytic effect was said to be less than that of the fresh serum. Thus 8 animals with tumours on the paws or flanks were injected with the anti embryonic serum, 4 of them were cured, and 2 showed improvement or arrest of development. Comparing the figures relating to treatment with fresh serum only it is seen that of 20 rats treated with specific serum 14 were cured, of 8 rats treated with embryonic serum 4 were cured.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 42. Isolation of Patients with Scarlet Fever

P. M. HOLST (*Lancet* & *Norsk Tidsskr.* April 15th 1927 p. 407) doubts the necessity of isolating patients with scarlet fever. In his Norway and Sweden the mortality from this infectious has fallen greatly during the last two or three generations but, though it cannot be claimed that isolation was more strictly enforced in Norway than in Sweden the great fall in the mortality occurred ten years earlier in Norway than in Sweden. The higher mortality in Sweden has continued since, it has only been twice as high in Sweden as in Norway. In November, 1910 the public health authorities in Bergen decided to discontinue the strict isolation and hospitalization which had hitherto been enforced. Scarletina henceforth being treated as lightly as measles and whooping cough, with the exception that notification and disinfection of the illness remained obligatory. By December 1925 the medical officer of health for Bergen could claim that the experience of the past sixteen years had given no reason for regretting this relaxation of the compulsory measures. As regards scarletina. As early as 1927 the public health authorities of Trondheim also relaxed the regulations concerning the isolation and hospitalization of cases of scarletina and again no ill effects were apparent. Since 1921 Svinger has followed suit, and with the same success. In Oslo however isolation has been maintained up to the present time and the tables published by the author show that Bergen has continued to suffer much less from scarletina than Oslo. The author concludes that the systematic isolation of cases of scarletina entails great sacrifices which in the present economic conditions it is difficult to justify. He thinks however, that it is probable that the disease will sooner or later change its character, and it may then be desirable to return to the former measures the necessity for which he doubts at the present time.

### 53. Infections Mononucleosis

J. E. COTTELL (*Ann. Journ. Med. Sci.* April 1927 p. 472) who reports twelve cases in patients aged from 13 to 26 with a review of the literature, states that the following are the salient features of infectious mononucleosis: (1) The usual general symptoms of an acute febrile disease of greater or less severity. (2) An increase in the lymphocytosis amounting to 40 per cent or more of the total leucocytosis. (3) Lymphadenopathy. (4) Angina in the form of hyperaemia of the fauces and pharynx or a severe ulcerative and exudative process involving tonsils, uvula or pharyngeal wall or all three. (5) Splenomegaly. (6) The frequent presence of Vincent's organisms in the ulcerative and exudative lesions. (7) Increase in the total number of leucocytes. The prognosis is invariably favourable and complications almost unknown. H. Fox (*ibid.* p. 486) records his observations on the histology of lymphatic tissue removed during the disease. There was marked hyperplasia especially of the small lymphoid cells and to a less extent of the small mononuclear phagocytosis of fragments but not the whole cells was seen. The lymphocytes appeared to be soft and degenerating. By intrastain staining the cells corresponded with the lymphoid elements. No monocytes were seen.

### 54. House Dust as a Cause of Bronchial Asthma.

A. H. POWE (*Arch. Int. Med.* April 15th 1927 p. 493) refers to his previous investigation of the etiology of bronchial asthma in children and young adults (see *Epitome* April 3rd 1926 para 359) and gives an account of his recent researches, which have led him to conclude that sensitization to house dust is by no means an uncommon factor in this condition. Skin tests with suspensions of dust were made in a series of 160 asthma patients, and positive reactions were obtained in 63. 20 patients with high fever also reacted. He found that a large number of patients had a characteristic history of dust sensitization, and he believes that dust react only in a dependent manner on one substance or on a summation of minor responses to several substances, such as animal emanations or root essences and various fabric dusts. That there may be an unknown specific substance in house dust is considered unlikely. Evidence was obtained that reactions to dust rarely occurred without one or more other reactions to proteins commonly used in testing. Rowe concludes that desensitization to house dust extracts which give definite reactions in the patient is probably advisable when a marked history of dust sensitization is present.

52

### Syphilophobia

A. JORDAN (*Lancet and Brit. Med. J.* April 1927 p. 234) states that this condition which was first described by Picard, may occur both among those with and without syphilis. Among 1,038 cases of syphilis which Jordan has treated in his private practice during the last thirteen years there were in all 71 cases (6.7 per cent) of syphilophobia. While however, in the period 1913-23 the number of cases of syphilophobia varied between two and six yearly in 1924 it rose to twenty-four, receding in the following year simultaneously with a decided fall in syphilis. In 1926 the number rose again to ten. Jordan's conclusions are as follows: There may be syphilophobia among the non-syphilitic as well as among the syphilitic and in both it may occur in a mild or severe form. As a general rule syphilophobia is a mild condition in non-syphilitic persons and a severe one in those who are syphilitic. In the non-syphilitic cases reassurance of the patient and explanation of the condition are usually sufficient while in the syphilitic psychotherapy must be combined with specific treatment.

53

### Tuberculosis and Intestinal Affections

J. A. SIEPMA (*La Med. Ibera* May 14th 1927 p. 531) does not agree with the usual view that there is an antagonism between tuberculosis and intestinal infections. He finds that tuberculosis and intestinal processes may coexist or follow one another in the course of an intestinal disease. Latent in the pre-tuberculous stage undergo a considerable aggravation of their condition if they contract typhoid or paratyphoid fever or a coliform infection. Intestinal disorders may in exceptional cases give rise to tuberculous sequelae in convalescence. Most intestinal infections of which the organism has not been discovered by laboratory methods are tuberculous processes. He concludes that every prolonged intestinal infection in which the Widal reaction is negative and no organism is found in the urine, faeces or blood should be regarded as tuberculous until the contrary has been proved.

54

### Toxin Antitoxin Immunization

J. L. LANN and E. C. BLACK (*Journ. Amer. Med. Assoc.* March 19th 1927 p. 895) state that Schick tests were performed on 15,562 of children belonging to the public schools of Kansas City with 8,687 (55.5 per cent) positive results. Of the 8,637 positive reactions 3,467 (23.6 per cent) of the total number tested were in boys and 7,200 (23.9 per cent) were in girls. Of the total number susceptible to diphtheria 3,553 children (38.6 per cent) were susceptible to both diphtheria and scarlet fever. Of those found susceptible 7,210 children (83.1 per cent) were given injections of toxin antitoxin. The result of this procedure has been that the number of cases of diphtheria has been reduced by 69.1 per cent since September 1925.

## Surgery

### 55. Phrenicotomy in the Treatment of Pulmonary Tuberculosis.

FLAPAD GUILLEMINET, and DE-JACQUES (*Lyon Chir.* March-April 1927, p. 134) discuss the value of the operation of phrenicotomy in producing collapse of the lung in pulmonary tuberculosis. By paralyzing that part of the diaphragm which rises up into the thorax the lesions are given rest the lung is allowed to retract and progressive sclerosis occurs in the affected parts. Though there is no such extensive collapse as in thoracoplasty beneficial results are obtained. The simple operation is attended with little risk and it practically always produces a very appreciable improvement in the condition of the patient. Combined with artificial pneumothorax it has also proved very satisfactory. In cases of tuberculous empyema it has been followed by notable improvement at once or when employed together with artificial pneumothorax. The authors state that in these cases the operation may be performed in three stages—namely aspiration of the pus, then phrenicotomy and finally thoracoplasty. This procedure has been followed by excellent results in patients severely ill.

56

### Torsion of the Gall Bladder

ACORDO and A. M. SHIPLEY (*Archives of Surgery*, May 1927, p. 953) torsion of the gall bladder is a somewhat rare condition. It is usually aches been partial and complete torsion. In complete torsion there is strangulation and gangrene.

whereas in incomplete cases the symptoms arise from interference with the drainage of the gall bladder, and more closely resemble those of chronic cholecystitis. The condition has usually been seen in females, particularly in elderly women who are thin and have relaxed abdominal walls. The volvulus may occur in either direction. In all cases the onset was sudden, with pain in the right side and vomiting. The outstanding feature was necrosis due to strangulation of the blood supply. The gall bladder was nearly always enlarged and distended. In only one instance was a correct diagnosis made before the operation. In many cases a mass was felt in the abdomen, jaundice was never noticed. Cholecystectomy was performed in most cases and without difficulty. Stones were found in a few cases, their presence is said to play no part in torsion and to be only incidental. The outstanding symptoms in all cases were pain and vomiting, fever was often absent and symptoms of shock were not present as a rule. The clinical picture is definite, but is rarely met with, and so is not usually considered.

#### 57 Treatment of Gastric Crises in Tabes Dorsalis

J. VERBRUGGE and L. VAN BOGAERT (*Lyon Chir.*, January-February, 1927, p. 22) discuss the division of the posterior nerve roots in the treatment of the gastric crises in locomotor ataxia. This form of treatment has been abandoned by many surgeons on account of the gravity of the operation and the frequency of post-operative recurrences. An examination of a number of patients shows that there are three types of pain: (1) the pain of root type, (2) the pain of sympathetic type (parietal pain), and (3) the pain of sympathetic visceral type (deep pain). Each of these three varieties corresponds to different groups of nerve fibres. Two cases are recorded in detail. In the first patient there were thoracic crises of the root type and gastric crises with extreme erythema. Paravertebral anaesthesia brought about instant temporary relief, and, following division of the seventh, eighth, ninth, and tenth dorsal nerve roots, a great improvement was maintained for three months, when death ensued from cachexia. In the second case division of the nerves completely relieved the vomiting and pain for nine months. The actual technique of the operation is described, based on the description given by Gaza, and the present authors conclude that this operation in severe cases of gastric crises is well worth consideration.

#### 58 Ossification of Operation Scars

R. DIDIER (*Gaz. des hop.*, April 20th, 1927, p. 525), whose paper contains a photograph of a case, states that the formation of bone in operation scars, first described by Askaniazy in 1900, is extremely rare. Bontou in his Paris thesis of 1926 was able to collect only thirty cases, and since then only one has been reported by Mornard, so that there are only thirty-one examples on record. In the great majority of cases men are affected, but the age of the patient is of no importance, and the ossification is found in the neighbourhood of the linea alba, especially after gastric operations. As regards the causation, operative trauma inflicted by section of the tissues, their compression by forceps, or perforation by needles, has been invoked. There does not appear to be any connexion between the ossification and post-operative haematomas and suppuration, nor does the nature of the ligatures used seem to be responsible. Experimental attempts to produce ossification in guinea pigs by violent muscular traumatism have hitherto failed. The prognosis of ossification of operation scars is favourable, the process does not show any tendency to spread, and the osteoma does not recur after removal.

#### 59 Gastric Cancer in the Young

H. G. MOGENA (*Arch. de med., cir. y esp.*, May 7th, p. 580), who records an illustrative case in a man aged 21, states that while the earlier statistics indicate that gastric cancer is rare in early life, more recent figures show that it has become increasingly frequent in the young. Thus in Bâle from 1870 to 1898 out of 666 cases of gastric cancer there were only 2 in patients under 30 years of age, and Welch found that among 2,975 cases of gastric cancer there were only 2 between 10 and 20, and 55 between 20 and 30. Gander collected 46 cases in young subjects from the literature up to 1904, and more recently Montier found 16 cases under 35 in a series of 100 cases of gastric cancer. In Spain gastric cancer appears to be relatively frequent in the young, as among 100 cases operated on by Garcia Pelaez 10 were under 35 and Urutia saw 8 below this age among 80 on whom an operation had been performed. The characteristic features of gastric cancer in early life are the absence of cachexia, the preservation of appetite, rise of temperature, and the rapid development of metastases, which renders its prognosis very grave.

## Therapeutics.

#### 60 Treatment of Thrombosing Phlebitis by Leeches

ACCORDING TO J. MONZON (*Prassi Med.*, May 28th, 1927, p. 677) the principal disadvantages of the use of leeches, apart from aesthetic considerations, are the inability to measure the quantity of blood extracted, and subsequent secondary haemorrhages. One leech will remove only from 2 to 4 drachms of blood, but after its detachment from the skin there will be a subsequent loss from the puncture of a further 25 to 50 drachms. These haemorrhages may occur not only at the point of application, but at other sites thus epistaxis may ensue, and, when more than one leech is applied, this may prove serious, especially in cardiac and hepatic cases. Tardy clotting of the blood, due to an antecoaagulant substance in the head of the leech, is the cause of these haemorrhages. This substance is easily extracted by mastication, and its subcutaneous injection produces the same effect as the leech, it does not act on the fibrinogen or coagulant formants of the blood, but is a powerful antithrombin. Monzon states that leeches can be beneficially employed in certain affections in which there is hypercoagulability of the blood. In post-operative and postpartal phlebitis, if applied when the first obliterating symptoms appear, they can abort this complication or considerably shorten its duration, four to six leeches should be applied to the morbid limb, the application being repeated two days later, and a third time if necessary. This interval of two days depends on the facts that the neoagulability of the blood appears in four to eight hours, reaches its maximum the next day, and lasts about forty-eight hours. The results of this treatment are a rapid cessation of the pain, fall of temperature, prevention of oedema, effacement of the venous cord, and a shortened duration of the malady. Ill effects are said to be rare and insignificant, local pruritus or generalized urticaria may occasionally develop. Leeches should not be used indiscriminately. In operation and postpartal cases when there is still danger of secondary haemorrhage, in established phlegmasia, and in severe infections their use is contra-indicated. Monzon holds that the effect of this treatment on uterine thromboses merits experiment, and maintains that, combined with antispasmodics, leeches constitute a rational therapy. He adds that it is important to exclude all possibility of meningeal or cerebral haemorrhage, in which event the action of leeches would be disastrous.

#### 61 Saline Injections in Mental Disease

T. MOROWOKA (*Journ. Mental Science*, April, 1927, p. 269) recommends the treatment of psychoses and neuroses by injections of the Ringier Locke solution, which contains the chlorides of sodium, potassium, and calcium, with sodium bicarbonate and glucose. He reports particularly good results in general paralysis, improvement in the mental functions and in sleep being associated with diuresis and more frequent evacuations of the bowels. Similarly, in dementia praecox patients were definitely benefited, though repeated injections caused rashes and occasionally abscesses, which did not, however, prevent the continuance of treatment. Other conditions which responded well were senile insanity, acute delirium, and manic depressive insanity. Injections of 1,000 c.c. of the fluid at a temperature one or two degrees above that of the body were given once or twice a week for a considerable period, and Morowoka emphasizes the importance of using sufficiently large doses. He states that Ikeda, who has employed this remedy in a large number of cases of mental diseases of different kinds, believes that the solution cleanses and removes the exogenous toxins and endogenous wastes from the body. It is suggested that with removal of the irritating toxins from the cerebral hemispheres improves the general nutrition of the nervous system and of various organs of the body.

#### 62 Treatment of Hypertension with Salt-free Diet

D. R. BLAISDELL (*London Med. and Surg. Journ.*, May 19th, 1927, p. 808) gives brief notes of 35 cases showing the results of a salt-free diet in arterial hypertension. No sodium chloride or bicarbonate was used either at table or in the preparation of the meals, and only those foods having the lowest salt content were chosen. After the initial elimination of salt the aim was to keep the twenty-four hour urine of salt at 0.5 gram, as a precautionary measure protein chlorides at 0.5 gram, as a precautionary measure protein retention of nitrogen. If the blood nitrogen was high the patient was put on a low protein diet for a few days and a strict salt-free diet was not prescribed at once, as a precaution against the precipitation of uric acid. The diet adopted was that advocated by I. M. Allen, and the results were much better than those obtained by low protein, salt-free diets, rest, and drugs. The disease appeared to be

by a margin of subdermal suppuration. The large papules were covered with dry blackish very hard crusts. The papulo pustular lesions were of smaller size on the scalp, forcarms, and thighs there were a few bullae. The child had had the eruption for one month and the papules were confluent. The general health was excellent. The mother had given the infant four or five teaspoonfuls of the sodium bromide in 1 teaspoonful of syrup. Although this was discontinued immediately the presence of 0.5 gram of traces of bromine immediately after the urine contained minute traces of bromine eight days later. The serous contents of thin lesions were free from bromine. The lesions healed slowly and some persisted for four weeks after the discontinuance of the syrup. Milhan thinks that the delayed recovery in these cases indicates that the condition is not an intoxication but an infectious phenomenon induced by the treatment he advises therefore boracic fomentations, boracic dusting powder and dilute lead lotion. He has obtained a rapid cure by applying tincture of iodine to the pustules.

69. H. OLTRAVIPE, J. GOLAY and A. STAROBINSKY (*Ann. de Dermatol.* April 1927, p. 193) reports the case of a patient with chronic acrodermatitis who was cured by an antogenous vaccine. They have only been able to find twenty-two cases in the literature. The condition is very chronic and resistant to treatment so that the cure obtained in the present case is particularly gratifying. The patient was a woman aged 45 who had suffered for a year before the vaccine treatment was started. No benefit had resulted from the previous treatment with penicillin and staphylococci were recovered on the hands injured and forty-seven injections were recovered. The vaccine was followed treatment for six months and there has been a relapse for the last year.

## Obstetrics and Gynaecology

67

W. IPECHERZ (*Dermatol. Hoch* May 7th 1927 p 65b) reports the case of a patient aged 23 who received an application of x rays for the epilation of the scalp at the back of the head where there was "crasis". Without any special simultaneous treatment there was a total disappearance of the psoriasis in this area. Total epilation was avoided. The patient was treated again eleven months later but on this occasion there was no epilation and the psoriasis areas were completely refractory. The author adds that you can not use a method of epilation which is supposed to be so antagonistic and so easily applied has the great objection that the eyebrows may disappear while the hair may persist in just those places where the psoriasis areas are most abundantly situated.

65  
Sugar Intolerance in Dermatoses.  
G G CAMPBELL and J. F. BURGESS (*Brit Journ Derm and Syph.*, May 1927 p. 137) refer to the well known association between diabetes and certain skin lesions in which treatment of the glycosuria improves the dermatosis. They have found that the temporary rise in blood sugar in intolerant subjects is an etiological factor in skin lesions mainly of the dermatitis type and that dietetic measures will cure such conditions where other measures have failed. The intolerance of some middle aged persons in sugar includes two separate factors: (1) inability to deal with more than a minimum carbohydrate diet without the blood sugar rising above normal limits (2) delay in the assimilation of sugar. They divide such skin lesions into two main groups—namely those developing during pregnancy and those occurring in pregnancy over the age of 50. They record two cases of matous intolerance in which the dermatitis was eczematous and mention two other cases in which it was urticarial. The authors state that in the senile type there is nothing in the skin condition to suggest that it is due to sugar intolerance but importance must be attached to the development of an intractable dermatitis in a person of middle age who was previously quite free. In some cases there was no apparent exciting cause whereas in others irritants such as soap and antiseptics to which the individual had long been accustomed caused the condition. In other cases there was no exciting cause the condition arising at unusual sites perhaps due to sugar in the perspiration. Where authors report thirty one cases in seven patients the known improvement was noted but the end results are not condition had completely cleared up the time varying from one to six months and six patients failed to report subsequently. Relapses due to dietetic indiscretions were cleared up by a return to a suitable diet. Many patients improved in general health and increased capacity for work. It remains uncertain whether the condition foreshadows diabetes in them. The authors conclude that the question of sugar intolerance as a factor in the production of dermatitis may have wide reaching application.

65. **Bromide Eruption in an Infant.**  
JEAN ELME and R BURNIER (*Bull Soc Fran de Dermatol*  
et de Syph March 1927 p 169) report the occurrence in an  
infant aged 4 months of a reddish purple papulo impetiginous  
eruption on the face scalp and forehead. The cheeks were  
chiefly affected the round or oval lesions ranging in diameter  
from a few millimetres to 3 centimetres they projected 1 or  
3 mm. above the level of the skin and were sharply defined

[illegible]

69 Surgical Anatomy of the Pelvic Sympathetic Nerve  
J DELVIG and G DE PALMISTE (*La Gynecol Marc* 1927  
p 129) in a description of the anatomy of the sacral  
nerve supply to the genito-urinary organs state that the  
"pre-sacral nerve of La Arjet corresponds with the superior  
hypogastric plexus of Horstmann and others. The pre-  
sacral nerve resection of which has been practised with  
some success in cases of dysmenorrhoea and pelvic neuralgia.

is formed at, or as far as one centimetre below, the bifurcation of the aorta (usually at the level of the lumbosacral disc between the fourth and fifth lumbar vertebrae) by the union of (1) a right root running down from the right renal and superior mesenteric plexuses between the right margin of the aorta and the inferior vena cava, (2) a left root having a similar origin and consisting of two or three small communicating trunks, and (3) a median root derived from the inferior mesenteric plexus. Exceptionally the "pre-sacral nerve," thus composed, constitutes a single ribbon-shaped trunk, more usually it is found in three or more filaments, forming a plexus in the angle between the common iliac arteries. The length of the "pre-sacral nerve" is from 5 to 6 cm., and after running down in front of the common iliac vein it terminates at the upper border or in front of the body of the first sacral vertebra by dividing into the right and left hypogastric nerves of Latarjet (the right and left internal hypogastric plexuses of Hovetacque). The "pre-sacral nerve" is thus in reality almost completely pre-lumbar. After its entry into the pelvis it becomes firmly adherent to the peritoneum, as do its terminal branches, to free the nerve in this region is difficult, and there is danger of bleeding from the median sacral vessels. On the other hand, during the upper part of its course the "pre-sacral nerve" is surrounded by a distinct sheath and is easily and safely separable from the adjacent great vessels.

#### 70 Backache in Women

F. SCHULTZE RHONHOE and H. WATRMANN (*Zentralbl. f. Gynäk.*, April 2nd, 1927, p. 842) emphasize the importance of flat-foot as a possible cause of backache in women. In the absence of any pelvic abnormality a general examination of the patient frequently discloses such conditions as pes planus, valgus, or plano valgus. While there is no difficulty about the diagnosis of well marked flat foot, lesser degrees are not so simple to recognize or to assess, and the gynaecologist should consult with an orthopaedic expert. The authors have been successful in about fifty cases, in which the backache ceased after the feet had been treated. Occasionally a gynaecological disability is found associated with flat foot, in these cases it is recommended to treat the feet first, since in many cases the backache will be cured and operative treatment avoided.

#### 71 Treatment of Uterine Fibroids

M. KAHN (*Surg., Gynecol. and Obstet.*, April, 1927, Part I, p. 569) discusses the question whether supravaginal hysterectomy in cases of uterine fibroid should be abandoned in favour of total hysterectomy, with special reference to the possible occurrence of carcinoma in the cervical stump. He states the arguments on both sides, and concludes that in all such cases the cervix should first be examined and the complete operation be performed if this organ is found to be deeply lacerated and infected, or even suspicious. If the cervix is normal, or can easily be made so, with not very deep lacerations or with mild erosion, the supravaginal operation may be performed with the cervical pathological condition has been corrected. During the performance of the operation for supravaginal amputation he recommends the examination of uterine smudgings, so that if the pathological report suggests the possibility of cancer the complete operation may be employed. He also insists that the uterine cavity should be examined immediately after a supravaginal amputation, in order that if a suspicious area is present the cervix may at once be excised. He believes that this procedure protects the patient reasonably well from subsequent cancer of the cervix and from an unnecessarily severe operation.

## Pathology.

#### 72 Globulin-Albumin Ratio of the Serum

GERRARD LEWIN (*Med. Klinik*, April 29th, 1927, p. 643) has estimated the globulin albumin ratio in 68 patients, using the refractometric method of Robertson. In most cases, at the same time, determinations were made of the sinking rate of the red cells by Linzenmeier's method, and blood films were also studied. The normal globulin albumin ratio used was 20-35 per cent globulin (Robertson). A globulin increase was observed in most pathological conditions. Of 9 cases of pulmonary tuberculosis 7 with good prognosis gave a globulin value as high as 59 per cent, two advanced cases shortly before death 83.7 and 77.9 per cent. In all cases of severe tissue destruction, acute infections, sepsis, pneumonia, osteomyelitis, and erythraemia from globulin value was raised. In 4 cases of pernicious anaemia the value was raised only

in one case, which was complicated by pyelitis. No correlation was found between the globulin value and the fall in the diazo reaction of the serum. From 76 comparative examinations of the globulin content of the serum and the rates of sinking of the red blood cells it appeared that the globulin value had but slight influence on the blood corpuscles in this respect.

#### 73 The Blood Fibrin Content in Pleurisy

F. BEZANCON, M. P. WILL, and C. O. GUILLAUMIN (*Ann. de Med.*, April, 1927, p. 302) for the estimation of the amount of blood fibrin have modified the method of Gram (*Journal Biol. Chem.*, December, 1921), the test being performed on the plasma obtained after centrifuging citrated blood, and not on whole blood. They found that the amount of fibrin in the plasma of the normal adult was 3 to 4 grams per litre of plasma, and considered as abnormal figures higher than 4 to 4.2 grams. The amount was slightly greater in females than in males. The blood fibrin was increased in many inflammatory conditions, particularly in pneumonia, acute articular rheumatism, erysipelas, scarlet fever, gonorrhoea, suppurations, and anginas. Its fibrin figure was found to be parallel with the temperature, it commenced to decrease slowly when the temperature fell, and the amount of fibrin was proportional to the severity of the illness. The authors state that in sero-fibrinous pleurisy of any nature the blood fibrin is always increased, rising to 5 to 7 grams and even higher. In pulmonary inflammation coexists with the pleurisy. A more marked characteristic than the intensity is the persistency of the fibrin increase. This continues long after the acute symptoms have ended. With the fibrin increase is associated an increased rapidity in the sedimentation of the erythrocytes, instead of the normal 250 minutes, 20 to 30 minutes is often sufficient for total sedimentation. These characteristics of great and persistent increase in the blood fibrin and increased rapidity of erythrocytic sedimentation occur also in rheumatism. In both these diseases, according to Gram, a close connection exists between the fibrin content of the blood and the rapidity of cell sedimentation—that is, between the fibrin content and the supralateral tension of the plasma.

#### 74 The Alveolar Carbon Dioxide in Pulmonary Tuberculosis

L. BERNARD, L. BINET, and H. R. OLIVIER (*Bull. et Mem. Soc. Med. des Hop. de Paris*, May 12th, 1927, p. 601) have estimated the tension of the alveolar carbon dioxide in fifty cases of pulmonary tuberculosis, using the Haldane-Priestley method. They find that in cases where the lesions are discrete the carbon dioxide tension of the alveolar air is normal, approximating 40 mm. of mercury. When the lesions are sufficiently extensive the condition modifies the chemical composition of the alveolar air. In cases of tuberculous fibrotic lesions, in consequence of the defective circulation of the air in the alveoli, the alveolar carbon dioxide tension and also the carbon dioxide of the arterial blood are raised, there is hypercapnia and gaseous acidosis. In cases with destructive cavitary lesions, as a result of the hyperventilation of the lung the alveolar carbon dioxide tension and the carbon dioxide of the arterial blood are lowered, there is acropnea and gaseous alkalosis. By repeated estimations on the same patients it was shown that the carbon dioxide tension of the alveolar air varied with the development of the lesion. The authors urge that then findings have a practical prognostic value and render possible the distinction between cavitary and fibroid types.

#### 75 Bacterial Charges during Immunization

A. B. WADSWORTH and G. M. SICKLES (*Journal Exper. Med.*, May, 1927, p. 787) have isolated a number of strains of pneumococci from horses which became ill during the course of immunization against the pneumococcus. The usual type of illness was a chronic septicæmia characterized by ulcers, two vegetations on the heart valves. The organisms were found to differ in many respects from the standard Type I strain used for inoculation. The authors bring evidence to show that as a result of their existence in the tissues they had become attenuated. Many had lost their virulence, and their virulence to mice, they were no longer type specific and they readily underwent phagocytosis in the presence of normal serum. The changes in virulence were especially interesting. Mice survived inoculations of 1 cc. of the strains. Of two mice receiving 0.5 cc. of the fifth strain, one died, from this an organism was isolated that proved to be a typical pneumococcus Type I, 0000001. The other organism was fatal to mice within twenty-four hours. In other words, a single passage through a mouse raised the virulence enormously. Whether these changes in pneumococci are to be attributed to the effect of the immune bodies, or whether they represent an adaptation to an adverse environment, has not been determined.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

### 76. Diabetes Mellitus and Concomitant Leukaemia

J. GLASER (*For Amer Med Assn*, May 21st, 1927 p 1626) reports a case of the simultaneous occurrence of diabetes mellitus and leukaemia and refers to three other similar cases in the literature. In none of the three cases was any evidence of leukaemic infiltration of the pancreas obtained by microscopic examination. In Glaser's case the pathological evidence of myelogenous leukaemia in the spleen and retroperitoneal lymph nodes, together with the qualitative changes in the blood picture without increase in the total leucocyte count defined the condition as myelogenous leukaemia of the leukaemic type. The patient's skin was markedly brown with darkening over the elbows and buttocks. This colour had appeared gradually during the six months before admission to hospital and there was no history of treatment by arsenic or rays. Glaser suggests that this unusual pigmentation may be due to disturbance of the sympathetic nervous system and through this of the suprarenal glands, by pressure of the enlarged abdominal lymph nodes on the abdominal sympathetic chains and ganglia. Alternatively it is possible that injury to the liver may have prevented the removal of melanin from the circulation. The diabetes responded at first to dietic treatment but insulin was required later. The patient gradually became oedematous pneumonia developed and death followed. At the necropsy red hyperplasia of the marrow of the humeri and the vertebrae was found. Extensive areas were present in the biliary duct and the right kidney and there was fatty degeneration of the liver without increase of connective tissue. The spleen and retroperitoneal lymph nodes were much enlarged, the suprarenals were rather small but their structure appeared normal. The pancreas was firm and lobulated with some increase of connective tissue. Mucinous islands of Langerhans were present and appeared healthy.

### 77. Sero prophylaxis of Measles

W. T. BRADSON and J. D. LAWRIE (*Edin Med Journ*, April, 1927, p 216) review the literature and record their observations at the Edinburgh City Hospital. Of twelve susceptible children from 1 to 8 years of age exposed to infection with the measles virus eleven escaped infection after passive immunization with convalescent measles serum on or before the fourth day of exposure, while one who did not receive the injection till the sixth day after exposure developed a highly modified form of the disease. The doses were 10 c.c.m. for children aged from 1 to 5 and 15 c.c.m. in a child aged 8. Of nine non-immunized children from 2 to 7 years of age, in whom the conditions of contact were even less intimate than in the other group two developed typical measles after a period varying from ten to fourteen days. In hospital practice the difficulty of obtaining an adequate constant supply of measles serum can be to some extent overcome by calling for volunteers among adult measles convalescents. In the absence of convalescent serum satisfactory results have been reported from intramuscular injections of whole blood obtained from parents, brothers, or sisters who have had measles at some previous date. In such cases the amount injected must be larger, varying from 15 to 30 c.c.m. according to age.

### 78. Physiological Constipation

G. LEVEN (*Full Soc de Ther*, April 6th, 1927, p 142 and *Gaz des Hop*, April 20th 1927, p 526) who records seven illustrative cases, in patients aged from 20 to 62 in whom the constipation lasted from six to twenty-two days states that a physiological as distinct from a pathological form of constipation occurs in patients whose nutrition is defective owing, to uncontrollable vomiting accidental or therapeutic diarrhoea or in acute infection with a prolonged high temperature. In such cases the constipation appears to be a reaction on the part of the organism to diminish its losses and to make the utmost use of the products of digestion before eliminating undigested products. It therefore appears to be analogous to the physiological oliguria observed under the same conditions when the dehydrated tissues retain the fluids at their disposal as much as they can. Physiological constipation has no bad effects. Leven treats such cases by ordering green vegetables and other articles with much indigestible residue and systematically orders sodium bromide and bismuth carbonate to check gastrointestinal spasms, laxatives, purgatives, and enemata are contraindicated as

they may transform this transient symptom into a pathological and permanent constipation. He adds that physiological constipation as a beneficial condition resembles some forms of diarrhoea, sweating, cough, and oliguria.

79

### Typhoid Fever in Children

D. HERDERSCHÉE (*Nederl Tijdschr v Geneesl*, May 7th, 1927, p 2468) records his observations on 541 cases of typhoid fever in children which occurred among 1,500 cases admitted to the Wilhelmina Hospital, Amsterdam in the course of the last eight years. Only 2 were under 1 year of age, 97 (49 boys and 48 girls) were under 5, 204 (113 boys and 91 girls) were aged from 5 to 10, and 240 (129 boys and 111 girls) from 10 to 14. The mortality was 2 per cent in children under 5, 4.4 per cent in those between 5 and 10, and 7.5 per cent in those between 10 and 15 as compared with 20 per cent in adult life. Necroses showed that as a general rule the intestinal lesions were less severe and extensive in children than in older patients. Clinical experience coincided with this finding as is shown by the fact that among 1245 patients above 10 years of age intestinal haemorrhage occurred 129 times, or in 10.4 per cent, as compared with 5 cases, or 1.7 per cent, among 301 children under 10. The complication itself was less serious in children than in older patients, as 70 of the 129 older patients or 54 per cent died but only 1 of the 5 children. Perforative peritonitis occurred in 33 or 2.6 per cent of the older patients and in only 2 (0.7 per cent) of those under 10. Operation was performed on 14 of the 33 cases, with 3 recoveries, and 1 of the 2 children was operated on and recovered. Phlebitis in the lower limbs during life was diagnosed in 48 (4 per cent) of the older patients, but was not seen in children under 10. Pelapses occurred in 7 children under 5 (7 per cent) and in 11 per cent of children aged 5 to 9. The same percentage was found both in male and female patients above 15 years of age. As a general rule typhoid fever was much less severe and of somewhat shorter duration in children than in adults but it might occasionally equal in severity the worst attack in adults. The results of bacteriological and serological tests are the same at all ages. The characteristic clinical features occur somewhat less frequently in children than in later life so that the diagnosis is not made so readily. The low incidence of typhoid fever in children, as recorded in statistics, does not therefore correspond with the reality.

## Surgery.

80

### Tumours of the Male Breast.

J. E. RAGUE (*Rev med de Barcelona*, April 1927 p 380) records four personal cases with a review of the literature and the following statistics of the relative frequency of cancer of the breast in males: 8 per cent (Lowenthal and Schnchardt) 9.18 per cent (Fonchon, Goret) 2 per cent (Winiwarter and Henry) 3 per cent (Jakoboff) 3.7 per cent (Schmitt) 2.82 per cent (Billroth) 2.8 per cent (Dietrich) 1 per cent (Judd and Morse Kellogg Speed). Among 103 cases of mammary tumour Rague himself saw three in men: a proportion of 2.97 per cent. Two were examples of typical adenocarcinoma and one was a fibroadenoma. Benign tumours are much rarer than the malignant, as David in 1922 could find only five examples of papillary cysts of the male breast on record in spite of the fact that this is the commonest form of benign tumour. One side does not appear to be more affected than the other. Of Rague's four cases three were on the right and one on the left side, while in Judd and Morse's seventeen cases seven were on the right and ten on the left. The age of the patient has a marked influence on the pathological form of the growth and the course and prognosis of the disease. In Rague's series in which the ages ranged from 18 to 75 the youngest patient had a fibroadenoma and the eldest a sarcoma. The following predisposing causes which were absent in Rague's series have been suspected: heredity, constitutional disease, mastitis, and gynaecomastia or polymastia. The symptomatology and operative technique are the same as in tumours of the female breast. Rague agrees with Judd and Morse in regarding the prognosis of mammary cancer in man as more unfavourable than in woman. Of his four patients the two with adenocarcinoma died eight months after the operation with pulmonary metastases, while the other two on whom the operation had only recently been performed, were still alive.

## 81 Primary Cancer of the Lung

K. FLRINCA and T. MATOLCSY (*Hien Hun Week*, May 12th, 1927, p 618) have inquired into the frequency and the reported increase of pulmonary cancer. Of 6,791 cases of malignant disease occurring between the years 1896 and 1925 the growth was situated in the lungs and bronchi in 282 cases. Expressed as a frequency curve for yearly intervals it appears that there has been a very remarkable increase in the number of cases of pulmonary cancer, and especially between the years 1920 and 1925. Comparing the percentage of these cases with that of all cases of malignant disease, they found that whereas in the period 1896 to 1901 the rate fluctuated between 0.54 and 1.97 per cent., in the period 1902 to 1914 it rose to 5.02 per cent., there was a further rise during the war period 1914 to 1919, and this was again increased in 1924 to 10.3 per cent. One third of the cases occurred between the ages of 50 and 60, and the incidence was nearly three times as frequent in men as in women. Of the 282 patients 43 per cent. were engaged in occupations in which the respiratory organs were especially exposed to injurious influences. In 44 cases the authors found signs of healed tubercle at the apices, or calcareous bronchial glands, and occasionally old cavities, they noted only one case of acute tuberculosis. Generally speaking, there was no causal relation between cancer and tuberculosis. Discussing the cause of the greater frequency of cancer they state that many authors associate the increase of pulmonary cancer in 1920 with the severe epidemic of influenza in 1918, others blame the increase of certain occupations in which irritant particles or gases are inhaled. The present authors conclude that this question is as yet unanswered.

## 82 Erosive and Gangrenous Balanoposthitis

E. R. PALMER (*Urol. and Cut. Rev.*, May, 1927, p 297), who records two cases with a review of the literature, states that the first adequate account of this disease was given in 1891 by Bataillo and Baidal, who reported more than 100 cases and demonstrated its contagiousness experimentally. The term "fourth venereal disease" was not suggested until several years later by Scheiber and Müller, who observed 50 cases within a year, and isolated a spirillum and vibrio from the penis and preputial exudate, thus confirming the findings of Bataillo and Baidal and establishing the existence of the disease as a clinical entity. Erosive and gangrenous balanoposthitis is an acute inflammatory affection of the glans penis and opposed preputial surfaces, characterized clinically by ulceration, erosions, and sometimes gangrene, with an abundant excretion of pus, which has a peculiar putrid odour, the organisms being morphologically identical with those found in Vincent's angina, noma, and carcinoma. Predisposing conditions are preputial redundancy favouring macerations, and partial or complete phimosis with exclusion of air, thus permitting accumulation and decomposition of smegma. Two forms of the disease have been recognized—namely, an erosive or ulcerative type and a gangrenous type. In the superficial and erosive type of the disease septic symptoms are trivial or absent. In the gangrenous form there is evidence of sepsis, but it is slight in comparison with the intensity of the infective process. The invariable initial manifestation is an itching or burning sensation of the glans penis and inner preputial surface. Subsequently oedema and phimosis occur and necrosis develops. Unless adequate treatment is adopted gangrene rapidly supervenes, causing destruction of the entire penis. Treatment should be prophylactic and curative. As Carbus has pointed out, the condition cannot occur in a person who has been circumcised. In mild infections, where the prepuce can be retracted, simple cleansing measures may suffice but in more severe types attended by phimosis dorsal incision is necessary and the parts must be kept clean by washing with dilute hydrogen peroxide.

## 83 Surgical Treatment of Gastric Ulcer

J. ABADIE (*Bull. et Mem. Soc. Nat. de Chir.*, May 7th, 1927, p 614) describes the results obtained in 300 operations for ulcer of the stomach. In 26 cases gastro-enterostomy alone was performed, with 2 deaths, in 264 patients duodenopylorectomy was performed, with 14 deaths, whilst in the remainder the ulcer was resected with or without an anastomosis, with one death. Of the patients, 285 were men and only 15 were women. Lung complications were less frequent in the later cases. In 45 consecutive cases no complication occurred after the operation. Abadie considers that resection of the ulcer alone does not cure the patient, gastro-enterostomy tests the ulcer and gives a good percentage of cures. Duodenogastrostomy is the operation of choice, it removes the ulcer and does away with any risk of malignant transformation. Spinal anaesthesia with local infiltration was employed and no morphine was given, ether was rarely used.

## Therapeutics.

## 84 Tryparsamide in General Paralysis

T. M. DAVIE (*Journ. Mental Science*, April, 1927, p 217) considers tryparsamide a most valuable therapeutic agent in general paralysis and in allied neurosyphilitic infections, its marked tonic effect being produced early in the course of treatment. He finds that it arrests the progress of dementia and prevents paralysis, mental improvement occurring in almost every case, though serological changes may be delayed until a long time after the cessation of administration. He has given intravenous injections of 3 grains once a week without untoward effects, as a rule, but he agrees that disease of the optic tract probably contraindicates its use. Slight transient pyrexia occurred sometimes, but in one case lasted for three days and was associated with haematuria. M. BROWNE and A. R. MARRIN (*ibid.*, p 225) have treated seventeen cases of general paralysis by tryparsamide, and report that the most significant results were disappearance of the psychoses, increase in weight, absence of seizures, and the conversion of dull and listless patients into useful individuals. Their results were obtained rapidly, and the improvement in the majority of cases persisted. They commenced with six doses, each of 1 gram, at intervals of one week, the injections being given intravenously in fifteen patients and intramuscularly in two. The dose was then doubled and eight injections were given at similar intervals. The authors conclude that a preliminary course of tryparsamide, followed by a malarial injection, is at present the most rational method of treatment, particularly of the debilitated early paralytic patient.

## 85 Onabain in Cardiac Insufficiency

J. WYCKOFF and W. GOLDING (*Irish Intern. Med.*, April 15th, 1927, p 488) record the results obtained in 32 patients with heart failure to whom 248 intravenous injections of the glucoside onabain were administered without harmful effects. The initial dose was usually 0.5 mg., followed every half hour by 0.1 mg. doses, and full therapeutic effect was considered to have been obtained when the ventricular rate was slowed to 80 or below. No patient who had received digitals within two weeks was given onabain. A definite result was obtained in 163 cases, the initial response being noted in from five to twenty minutes and the maximum in from fifteen to fifty, it was found that the larger the dose the earlier the initial response and the more delayed the maximum effect. A greater amount of the drug was needed to reduce the ventricular rate in patients with auricular fibrillation accompanied by fever than in those in whom there was no rise of temperature. The persistence of action of the drug varied, but except in three cases it never exceeded five days. Full therapeutic digitalization was produced fifty-two times in thirty-two different patients, and in only three were mild toxic symptoms noted—namely, premature ventricular contractions in one and vomiting in two. The authors conclude that if given in fractional doses onabain may be safely administered intravenously to patients with auricular fibrillation who have not recently been given digitals. They add that since clinical improvement seems to be the only criterion for full therapeutic effect, in patients with regular sinus rhythm special care must be exercised, and they mention the danger of overdosage in moribund patients who may not show clinical improvement.

## 86 Tissue Dehydration Treatment of Pulmonary Suppuration

J. MOUZON (*Picess. Med.*, May 14th, 1927, p 615) recommends the following treatment of broncho-pulmonary suppuration of a non-tuberculous nature. An abundant salt-free diet is given, but the daily quantity of liquid is reduced to from 200 to 400 ccm. Discomfort due to thirst is relieved by orange juice or acid drops. After three days' treatment of these lines the fluid intake is increased to 1,200 to 1,500 ccm. for one day, and then the dry regime is begun again. The course is continued for four to six weeks, with two "detoxifying" days a week. The urine diminishes, but remains, as a rule, in excess of the liquid taken. The weight also decreases, but is rapidly restored at the end of the treatment. From the first the sputum diminishes, it generally becomes of a serous or 11 patients with chronic purulent bronchitis, and 11 whom were cured and remained so for at least a year, and 11 of 22 patients with post-influenzal lung abscesses, 19 of whom were cured within three weeks. He adds that the treatment is useless in tuberculous cases and is contraindicated in doubtful value in cases of purulent pleurisy and cavity.

## 87 Testicular Extract in Ovarian Neurosis

V DU LAUPH (Arch. Med. Sci., April 20th 1927 p 597) believes that psychical troubles due to ovarian insufficiency or dysfunction are very common particularly in women of the more intellectual type. Most patients present a neurotic-like syndrome in which melancholia, obsessions and fears predominate, the periods of depression sometimes alternate with phases of excitement. Phases of a neurotic type are usually present and are almost always localized in the pelvic lymphatic system and the lower limbs. Some measure of success has been obtained from treatment with extracts of the corpus luteum or of the whole ovary, but for some years Du Lauph has obtained better and more reliable results by the employment of testicular extract. This drug is administered either by the mouth in tablet form or by intramuscular injection, the two methods being sometimes combined. He describes six cases in which this treatment was adopted and cure established, and maintains that in the depressive conditions amelioration and often complete cure, follows the use of this form of therapy.

## 88 Treatment of Jaundice by Insulin

FICHTZ (Arch. de med. exp. April 30th 1927 p 558) states that in addition to its use in diabetes mellitus insulin has been successfully employed for the following conditions: diabetes insipidus (Vitt), Graves' disease (Feyn and Parurier), shock (Lieber and Snel), alimentary intoxication in children (Lieber and Wagner), induration (Lieber), Marfan's, dermatoses (Ravint), chronic rheumatism (Lieber), Erythema, and Lactaria hyperaemia (Lieber and Cadenas). Fichtz now reports a case of icterus in a girl aged 13, who presented signs of hepatic insufficiency in the form of icteroid and disturbance of the carbohydrate metabolism revealed by slight glycosuria. Ten units of insulin were injected daily for six days, one hour before meals which consisted mainly of carbohydrates, a small quantity of protein and no fat. On the day after the last injection of insulin the acidosis disappeared and only traces of glycosuria remained. These were absent on the second day of treatment, when the jaundice began to fade, completely vanishing within a week.

## Radiology.

## 89 X Rays in the Diagnosis of Gas in Intestinal Perforation

M H TODD (Amer. Journ. Surg. May 1927 p 449) advocates the routine radiographical examination of all cases of suspected perforation of the gastrointestinal tract on the grounds that the presence of air or gas in the peritoneal cavity can be demonstrated thus with certainty. He gives details of ten cases, all but one of which were traumatic. He believes that a consistently negative series of findings definitely contraindicates perforation except in appendicitis cases and possibly in perforation of the stomach. The technique employed was simple: when all preparations had been made the patient sat up for a moment, a film was placed anteriorly to show the lower part of the chest and upper part of the abdomen, double screens were used and the patient was instructed to hold the breath for a moment in order to fix the diaphragm. In this last being considered a most important point. Gastrointestinal perforation was indicated by the presence of a gas bubble above the liver. Todd considers this the most characteristic simple sign of perforation. He adds that the condition is easily demonstrable, even when the hole is minute and very early diagnosis is made possible.

## 90 Radiological Diagnosis of Hilum Tuberculosis

G DETRE (Journ. Radiol. et d. Electrol. May 1927 p 257) comments on the value of obtaining both frontal and antero-lateral radiographs of the chest in cases of suspected hilum tuberculosis in children, though he admits that it is not possible to prevent confusion being caused sometimes by hilar shadows falling on the ear space between the heart and the vertebral column. It is possible however in this way to detect and distinguish such conditions as adenopathy, perianitis and hilar tuberculosis. In some cases with suspicious symptoms and signs it is found that the pathological process is old or quiescent or that there is no evidence of tuberculosis. Detre discusses the different appearances shown by radiographs taken in the two directions mentioned and gives illustrations of the more typical pathological processes thus defined. The value of this method of examination in prognosis is also indicated.

## 91 Diathermy Coagulation in Radiologists' Cancer

H LORNIER (Acta Med. Scand. April 30th 1927 p 291) reports the cure of a cancer in a radiological worker who since 1925 had been exposed to small doses of x rays. His hands free therapy and particularly his eye receiving variable doses of the rays. In 1927 small keratomata appeared on the left hand and a year later the first eyelid lesion. In 1928 an abortive attempt at skin grafting after excision was made and two years afterwards there was a recurrence of the growth. The tumour became malignant, and in 1926 formed a swelling of about 1 cm. in the angle between the first two fingers of the left hand, it gave rise to a febrile, ichthyous discharge and prevented scintillation of the digits. After local anaesthesia with a cocaine diathermy-coagulation of the greater part of the cancer was performed, the intensity employed varying from 150 to 400 milliamperes, three minutes' application was sufficient to coagulate the tumour. An abundant lymphorrhoea lasting for two days was produced by the operation and all pain ceased from that time. The diet consisted of carbon oil and 1 percent carbolic oil daily irrigations with boric isotonic saline solution were employed. Fifteen days after the operation the large eschar came away and in six weeks cicatrization was almost complete. A second coagulation was performed in order to destroy the remaining tumour particles and a month later the cure was definite and complete. Border lesions that x-ray lesions especially if ulcerated should not be treated with radium as a radium dermatitis will be superimposed on the existing cancer producing radio-dermatitis, which renders cicatrization even after diathermy-coagulation, very difficult and often impossible to obtain.

## 92 Skiagraphy of the Spleen in Newborn Infants

P FILLAT (Lyon. med. May 15th, 1927 p 553) believes that enlargement of the spleen in a newborn infant is as valuable in the diagnosis of congenital syphilis as a positive Wassermann reaction or an epiphyseal osteochondritis. It is not always present however and the splenic hyperplasia varies greatly in degree. Frequently it is impossible to palpate an hypertrophied spleen in a newborn infant. In a healthy infant the spleen is quite small, measuring approximately 1 cm. horizontally, about 2 cm. vertically and 1 cm. in depth. Its mean weight is 6 to 10 grams. In congenital syphilis it weighs frequently 20 to 25 grams and its dimensions are three times the normal measurements. Trilobate and the splenic tissue is impermeable to x-rays. The shadow is best seen by turning the child slightly on the left side. This gives a better definition of the organ which then projects over the outlines of the ribs. The shadow of the normal spleen is often indefinite, lying below the diaphragm and moving with it, it appears as a small slightly triangular object corresponding at the maximum to two or three intercostal spaces.

## Obstetrics and Gynaecology.

## 53 Hypertension in Pregnancy

E J STIEGLITZ (Arch. Intern. Med. April 1927 p 465) has investigated the relation of the calcium content of the blood to the etiology of hypertension in pregnancy. He made 222 blood calcium determinations in a series of cases including normal pregnant women, pregnant women with hypertension and non-pregnant controls. The arterial tension was observed in each instance at the time the specimens of blood were obtained, as far as possible the observations were made at the same time of day, usually in the mid-afternoon. The cases were ranged in the following four groups according to the character of the hypertension: (1) A relatively benign type occurring moderately early in pregnancy characterized by a gradual rise in arterial tension and little evidence of serious intoxication. There were 29 cases in this group which constituted the so-called nephrosis of pregnancy. (2) A later malignant type with sudden rapid rise in arterial tension and evidence of marked intoxication, quickly becoming a triad with hypertension, headache and vomiting. (3) Hypertension in patients with pre-existing vascular and usually renal disease both undergoing exacerbation during pregnancy. (4) Hypertension in pregnancy with definite complications such as toxic gout, cardiac disease and acute nephritis. Stieglitz's conclusions are as follows: (1) Hypocalcaemia is not of major etiological significance in arterial hypertension in pregnancy. (2) During the last month of pregnancy a gradual rise in arterial tension associated with a moderate hypocalcaemia. (3) Immediately after parturition a fall in blood pressure occurs with a corresponding rise in the blood calcium concentration. (4) Simultaneous with the onset of lactation a secondary rise in arterial tension occurs with a corresponding and equally transient hypocalcaemia.

## 94 Treatment of Menorrhagia

H. SACHS (*Centralblatt f. Gynak.*, May 14th 1927, p 1242) reports 100 cases of severe menorrhagia treated by x-rays. All the patients were subjected to a preliminary curettage to exclude such conditions as malignancy, polyp, and submucous myomata, all except three were over 40 years of age. Sachs thinks that it is almost impossible to sterilize permanently a woman under 40 by means of x-rays. Physiological cessation of menstruation is said to be due to insufficiency of various internal secretions. The specific hormone of menstruation is produced in the Graafian follicle, which is attacked by x-rays, the activity of the cells is overstimulated until death ensues. The cases were divided into those treated during the menstrual period and those treated in the intermenstrual period. In the first class, with very few exceptions, there was instant and lasting amenorrhoea, while in the second class there were often two or even more severe periods after the treatment, but the method was always successful in the end, and Sachs adds that a temporary increase of menorrhagia should not deter either the patient or the physician.

## 95 Post-climacteric Haemorrhage.

M. MUIET (*Gynecol. et Obstet.*, April, 1927, p 241) restricts the term post climacteric haemorrhage to bleeding supervening more than a year after the menopause, whether physiological or post operative. He thinks that the importance of post climacteric haemorrhage is insufficiently recognized in practice, and that a complete examination is necessary to discover the actual cause of the disease. Crises of post climacteric haemorrhage are rare, and the causes are often mechanical in origin, a venous congestion due to prolapse may lead to ulceration and haemorrhage. Between 1896 and 1924 Muiet investigated 312 cases of post climacteric haemorrhage, of which 79 were due to malignant disease, cancer of the uterine body providing 42, and epithelioma of the cervix 37. Muiet remarks that this indicates the importance of thorough investigation of every case if the cause of haemorrhage is not discovered elsewhere the uterine cavity should be curetted and the scrapings examined histologically. Curetting in aged women requires great care, as the uterine walls may be thinned by senile atrophy or a neoplasm, so that perforation may occur. The author prefers Hegar's dilators to laminaria tents, digital examination appears to him useless and dangerous. Among his 312 cases he found 61 cases of utero vaginal prolapse, thus malignant disease and prolapse accounted for nearly 45 per cent of all cases. Other comparatively frequent causes of post climacteric haemorrhage were polyp and adenomata (41 cases), 8 cases were due to cervical erosion. Muiet emphasizes the favourable prognosis in cancer of the body of the uterus when total hysterectomy with ablation of the adnexa is performed, he adds that it is therefore most important to lose no time nor to neglect even a single slight haemorrhage. In cancer of the cervix this prompt action is still more necessary, as the disease progresses more rapidly and the prognosis is less favourable. The possibility of cancer must be eliminated, if necessary, by repeated curettings and histological examinations before the haemorrhage is attributed to disease of other organs.

## Pathology.

## 98 Etiology of Pulmonary Gangrene

E. SERGENT, H. DURAND, and MOISESCO (*Journal de Med. et de Chir.*, May 10th, 1927, p 305), rejecting the view of Delamare, Bozancan, Vincent, and others that spirochaetes are the chief causal agents of pulmonary gangrene, hold that anaerobic bacteria are the true cause of this condition. These bacteria, which give rise to necrosis and fermentation, are always found in massive gangrene, while spirochaetes are rarely present, and moreover, are found in other pulmonary conditions. The present authors agree, however, that spirochaetes may initiate gangrene, often of bacillary origin, they gain entrance to the respiratory tract causing an ulcerous broncho-pneumonia, which opens the way for secondary infection by anaerobes. Suppuration with abscess formation supervenes. If the abscess is badly drained or the fissure closed, suppuration proceeds in a closed chamber and anaerobes multiply, with the subsequent production of fetor and gangrene. Other conditions, such as purulent bronchitis, pneumonia and bronchoectatic abscess should not be confused with gangrene, and the authors assert that a true diagnosis can only be reached by an attentive analysis of clinical symptoms. Regarding treatment, no benefits have been obtained from the use of vaccines, anti-gangrene serum, or arsenical salts, and surgical intervention is always necessary. Pneumothorax has been tried with some success, the danger here being in infection of the pleura owing to rupture of the

infected focus. Ablation or destruction, rather than opening of the gangrenous area, should be aimed at. If the lesion is small and well localized, thermocoagulation or electrocoagulation is advisable, but when the area is large external pleural compression may be useful. Phlebotomy gives relief, and is a useful preliminary to a more direct and radical operation.

## 97 A Leukaemic Blood Picture in Syphilis

R. C. LAPRABEE and N. SIDEL (*Boston Med. and Surg. Journ.*, May 5th, 1927, p 730) describe a case of syphilis which, on admission to hospital, was considered as a probable myelogenous leukaemia. The symptoms were weakness, slight cough with purulent sputum, increasing dyspnoea, and marked pallor of the skin and mucous membranes, with a generalized brownish yellow discoloration of the face. The blood findings were haemoglobin (Sahli) 30 per cent, erythrocytes 1,640,000, leucocytes 55,800, and platelets 282,000. A differential leucocyte count showing 17 per cent lymphocytes, and 9 per cent myelocytes. A Wassermann test and x-ray examination led to the correct diagnosis, the former being strongly positive and the latter revealing marked thickening and irregular shafts of both femurs and clavicles and multiple punched out areas in the outer table of the skull. Intensive treatment with sulpharsphenamine (thirteen intravenous injections being given) caused a rapid recovery in seven weeks. On discharge the haemoglobin was 85 per cent, the erythrocytes numbered 5,046,000, and the leucocytes 7,000, with 1 per cent myelocytes. Kummblair has recently reported ten cases in which the blood pictures were indistinguishable from leukaemia, these show that acute infections may be so severe that myelocytes, or even myeloblasts, may appear in the blood as a result of unusual strain on the bone marrow. In the present case this bone marrow have been caused by the spirochaete of syphilis. The case emphasizes the facts that syphilis may present bizarre forms, and that a leukaemic blood picture does not necessarily imply the existence of true leukaemia.

## 99 The Effect of Quinine on Metabolism in Diabetes

SILBERSTEIN, TATUM, and CUTTING found that doses of 0.07 to 0.1 gram of quinine per kilogram of body weight produced hypoglycemia in animals. A. LOW and R. P. FIDELL (*Bull. Clin. Med.*, April 21st, 1927, p 526), on the other hand, working with much smaller doses—that is, 0.005–0.01 gram per kilogram injected intravenously—obtained a reduction in the blood sugar. In normal human subjects they found that the blood sugar began to fall twenty minutes after an intravenous injection of half a gram of quinine hydrochloride, reached a minimum in 40 to 160 minutes, and returned to its original level three to four hours after the injection. Similar results were obtained in mild and moderately severe cases of diabetes, with parallel effects on the amount of sugar excreted in the urine. The total ketone bodies in the blood were also found to be reduced, except in one case of severe ketonuria, which was unaffected. In the only two cases of diabetes in which it has so far been tried the oral administration of 0.25 gram of quinine hydrochloride four times daily with a standard diet also effected a reduction in blood sugar, acetone bodies and glycosuria. Low and Fidell conclude that since quinine appears to have an effect on carbohydrate metabolism comparable with that of insulin, other compounds unrelated chemically to insulin may have a similar action, and the investigation of all these is likely to throw light on a number of problems connected with the action of insulin.

## 99 The Kahn Test for Syphilis

F. BERRY, L. E. LY, and G. M. DILLON (*Journal Amer. Med. Assoc.*, April 23rd, 1927, p 1306) have performed a series of 15,000 Kahn tests in order to determine the diagnostic reliability of this procedure, its sensitiveness, and its source of error. They find that the test is as specific as, and more sensitive than, the Wassermann technique, it is also simpler and the diagnosis is obtained more rapidly. The authors add, however, that as much skill and experience in serology are required for the performance of the Kahn as of the Wassermann test. In their investigations they obtained a complete agreement between the Kahn and Wassermann reactions in 89.13 per cent, relative agreement in 6.54 per cent, and complete disagreement in 4.33 per cent. J. L. W. (ibid., May 7th, 1927, p 1469) reports, as the result of fifteen months' experience of the Kahn precipitation test, that its absolute diagnostic significance can be attached to the result in any individual case, though the stronger a positive result is the greater is the probability of the patient being a syphilitic. He considers that the functions of the test in the diagnosis of syphilis are to suggest the possibility of this disease in persons in whom it was not previously suspected, and to contribute confirmatory evidence when the diagnosis is in doubt. He prefers the Kahn to the Wassermann test by reason of its technical simplicity and greater promise of uniformity.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine

### 100. Post encephalitic Respiratory Symptoms

L. HESS (*Wien Klin. Woch.*, May 25th 1927, p. 670) describes the respiratory symptoms which may occur in the chronic stage of epidemic encephalitis. Occasionally post encephalitic Parkinsonism is associated with a more or less permanent condition of hyperpnoea with increased depth and rate of respiration unaccompanied by subjective symptoms of dyspnoea. Intoxyminal attacks of hyperpnoea of sudden onset, generally lasting several minutes during which the respiratory rate is 30 to 40 are however much more frequent. These attacks are sometimes preceded by motor restlessness or other prodromata and while they last the lungs are hyper- resonant to percussion and the liver dullness appears to be diminished sometimes a few rhonchi or subcrural rales are audible at the bases. The heart rate is only slightly accelerated and cyanosis is not a marked feature. A small amount of watery sputum is expectorated at the end of the attack but there is no associated cough or laryngitis, though a bad attack may be followed by vomiting. These attacks may occur at any time of the day or night at irregular intervals as many as six in the course of twenty-four hours were observed in one case. The sudden onset and subsidence of the attacks together with the absence of cyanosis and of evidence of organic change in the heart or lungs in the intervals point to a nervous origin. They differ from attacks of bronchial asthma in duration, irregularity of occurrence and the character of the respirations. In the Parkinsonian type the excursions of the diaphragm are small and frequent and inspirations and expirations succeed one another regularly and rapidly whereas in bronchial asthma the respiratory rate is often diminished and expiration prolonged, while there is hypersecretion of the characteristic sputum. Hess explains this difference by the hypothesis that the motor and secretory symptoms of bronchial asthma are produced by peripheral irritation of the vagus while the Parkinsonian attacks are of central vegetative motor origin. He compares them with the air hunger of diabetic coma and of the alimentary intoxication of infants, or the paroxysmal attacks occurring in pernicious anaemia, early cerebral atherosclerosis and Graves disease, which are all probably of cerebral origin. Macroscopic evidence of lesions in the locus ceruleus forms an anatomical basis for this hypothesis.

### 101. The Dick Test.

H. D. LEES (*Journ. Amer. Med. Assoc.*, April 9th 1927, p. 1133) found that of 48 scarlet fever patients, 15 (31.2 per cent) had negative Dick reactions at the onset of the disease. A negative reaction, therefore, did not seem to be a reliable index of immunity to the disease and could not be relied on as an aid in the diagnosis of doubtful cases of scarlet fever. Out of 530 students from rural districts whose average age was 17 years, 264 (49.8 per cent) gave a positive reaction. Of 120 positive cases 76 (63.3 per cent) were rendered Dick negative by active immunization with one injection of 3 CCG skin test doses of toxin detoxified with 2 per cent sodium bicarbonate. Lees found that intradermal injections of convalescent serum produced an earlier and more complete local blanching of the scarlet fever rash than did the concentrated antitoxin prepared by the Dick method. In four out of five students who received prophylactic doses of scarlatinal antitoxin the Dick test remained positive.

### 102. Temporary Disappearance of the Dick Reaction

R. DEBRÉ, M. LAMY and H. BONNET (*C. P. Soc. de Biologie*, June 24th 1927, p. 104) have found that in patients affected with various exanthemata a positive Dick reaction often becomes negative this being particularly the case in measles. They cite the cases of four infants in whom a positive Dick test became negative on the day following the appearance of the measles rash. Absence of the specific antitoxin in the serum was also noted. Numerous tests performed about every two days proved that this disappearance of the reaction was only temporary and that it again became positive at the end of a month. According to the authors other exanthemata cause this phenomenon and a similar result was obtained in an infant suffering from an acute erythema following treatment by quartz lamp irradiation for rickets. The authors believe that these temporary changes can be observed in any cutaneous eruption and that they are in no way specific. A weaker Dick reaction has been noted over skin treated with sinapism than over normal skin. They

consider that the Dick test is liable to give erroneous results in exanthemata, and particularly in measles, and that in such cases it should be replaced by one for the presence of antitoxin. These views are in accordance with the recent findings of Carnot, Lenard, Biancamani, and Azerard as to the retarding action of ultra violet rays on the cutaneous reaction to tuberculin.

### 103. Chronic Ulcerative Colitis

P. ALESSANDRINI (*P. Policlinico Sez. Prat.*, May 22nd 1927, p. 743) discussing the etiology of this disease states that there is often no evidence of pre-existing amoebic or bacillary dysentery. In some cases excretion of material taken directly from the ulcers by means of a sigmoidoscope may solve the etiological problem and the agglutination test is sometimes helpful. The symptom of chilliness occasionally observed in colitis as in cholera is possibly of anaphylactic origin and the cool tongue may be an indication of an attempt at the elimination of toxic substances by epithelial desquamation rather than a direct consequence of the intestinal condition. The author thinks that the diet in these cases need not be too restricted but frequent examination of the stools is necessary. The most useful drugs are emetine, ipecac and stovaine even if there is no amoebic infection. Specific serotherapy does not seem to give better results than non-specific protein therapy. The children's suggestions of the existence of some relation between the skin and colon, and violet rays have proved beneficial occasionally but if used, they must produce a denude cutaneous erythema for good to be of use. In haemorrhagic cases opium and haemostatics are necessary, enemata are believed to act chiefly by removing mucous and necrotic fragments rather than by direct action on the ulcers. The moderate use of laxatives is advised. Surgical treatment such as appendicectomy, caecostomy or anastomosis on the whole gives poor results when one particularly resistant patch prevents cure.

### 104. Anthocyaninuria.

M. W. POOLE (*Amer. Journ. Dis. Child.*, May, 1927, p. 765), who records an illustrative case describes this rare condition which signifies pigmentation of the urine following ingestion of red beet (*Beta vulgaris*) and may readily be mistaken for other conditions in which red pigment occurs in the urine. According to Formanelli the red of beetroots is caused by anthocyanin, which changes to yellow under certain conditions the absorption bands of the yellow pigment being identical in position to carotin. The cause of the change being unexplained. Poole's case occurred in a boy aged 6 in whom the presence of the dye in the urine following ingestion of beetroots was probably the result of a change in permeability of the kidney due to scarlatinal nephritis as it had never appeared previously.

### 105. Periarthritis Nodosa.

H. A. SINGER (*Arch. Int. Med.*, June 15th 1927, p. 865) discusses periarthritis nodosa with special reference to the acute abdominal manifestations and reports two cases. It is generally believed that the condition is an infectious disease caused by a filterable virus or a number of different agents but that syphilis plays no part in its etiology. Most cases are not diagnosed during life and are only revealed at the necropsy so that the pathological side has been dealt with far more exhaustively than the clinical. The bewildering symptomatology may be simplified by assuming the presence of an infectious process which in addition to causing local symptoms based on circulatory disturbances in the systems or regions affected also produces such constitutional disturbances as fever, tachycardia, eruptions and leucocytosis similar to those of a chronic septic process with either acute or insidious onset. The symptoms due to local vascular changes vary according to the system involved but as a rule several systems are simultaneously affected. Limitation of the manifestations to one organ being exceptional. Abdominal symptoms especially those referable to the gastro-intestinal tract are almost always present and when multiple lesions exist it is almost impossible to determine the cause of the pain which is frequently extremely severe. Nodules in connection with the cutaneous vessels representing either granulomatous thickenings or thrombosed aneurysmal dilations are important diagnostically and rupture may cause cutaneous haematomata. Pain in the upper abdomen may suggest ruptured peptic ulcer or pancreatitis while in the lower abdomen it may give rise to suspicion of appendicitis. The appearance of cutaneous nodules is generally the first

due to a correct diagnosis, and when these are absent the real condition may not be revealed except at operation. Usually chronic and progressive in its course, its duration averages about two months, marked by irregular exacerbations and remissions, while latest statistics point to recovery in from 10 to 12 per cent of the cases.

### 103 Primary Pneumococcal Meningitis

J CHALIER and R PUIG (*Journ de M d de Lyon*, June 5th, 1927, p 281) state that pneumococcal meningitis, which was first described by Nettel in 1887, may be either secondary to another focus of pneumococcal infection, such as pneumonia or mastoiditis, or be primary, in which case the portal of entry of infection is doubtful. Primary pneumococcal meningitis is less frequent than meningococcal meningitis or pneumococcal meningitis secondary to another source of pneumococcal infection such as pneumonia or mastoiditis. Clinically pneumococcal meningitis is more severe than meningococcal meningitis, and is almost always fatal, whether its form is purely meningeal, apoplectic, fulminant, or insidious. A few rare cases of recovery, however, have been recorded. The authors record two cases, in patients aged 16 and 24 respectively, in which the presence of the pneumococcus in the blood was established by direct smears and cultures. This pneumococcus septicaemia is analogous to the meningococcal septicaemia found in meningococcal meningitis. Authorities are divided as to whether infection of the meninges in these cases takes place by the same pharyngeal route through the otiticoid, or, as is more probable, by the blood stream. The intravenous injection of serum is of great value in these cases, and should always be employed in addition to intraspinal serotherapy. Although, as a rule, antipneumococcal serum is ineffective, Cruevillier has reported a case of pneumococcal meningitis in which improvement set in as soon as intravenous injections were given, the patient ultimately recovered.

### 107 Tertiary Syphilitic Fever

VILAPLANA (*La Medicina Ibera*, April 30th, 1927, p 476), records an illustrative case, quotes M Bloch's statement that a diagnosis of pure or essential syphilitic fever may be made under the following conditions: (1) a febrile state of a pseudo malarial type, (2) slight degree or entire absence of physical signs, (3) a positive Wassermann reaction in the blood, (4) rapid disappearance of the fever under antisyphilitic treatment. Vilaplana's patient was a soldier who presented fever of an intermittent type and a positive Wassermann reaction in the blood. It was, however, impossible to say whether this was a case of tertiary syphilitic fever, as the man was both syphilitic and malarial, antisyphilitic treatment was not continued long enough to have any effect.

## Surgery.

### 103 Spontaneous Rupture of Abdominal Muscles

H KRASSO (*Wien Klin Woch*, June 9th, 1927, p 751) records two similar cases—in a woman aged 73 and a man aged 70. Both were obese persons with pulmonary emphysema and arterio sclerosis. As the result of a violent expiration—a cough in one and a sneeze in the other—violent pain occurred in the left iliac region, which was aggravated by movement and pressure. Some days later a haematoma appeared at the painful spot, though it was at first mistaken in one case for erysipelas and in the other for haemorrhagic herpes zoster. Both patients recovered as the result of rest in bed and treatment for the cold which was the cause of the disease. There was no doubt that the condition was due in both cases to laceration of the fatty degenerated external oblique muscle and its fascia, as well as of some of the small subcutaneous arterio sclerotic vessels, as the result of the mechanical strain caused by coughing and sneezing.

### 109 Primary Tumours of the Knee-Joint.

F HABITZ (*Vojsk Mag f Laeqevd*, May, 1927, p 369) describes the following varieties of primary tumours of the knee joint: (1) Primary diffuse sarcomata in the synovial membrane (two cases). The first case was that of a man, aged 22, who in the course of seven or eight weeks developed a diffuse swelling of the knee resembling tuberculous arthritis. On resection of the joint the synovial membrane was found to be uneven rough, and granular, and to present brownish tufts with calcareous incrustation. On microscopic examination quantities of calcareous granules were found in a tumour-like tissue closely resembling a mixed celled sarcoma. Remission soon followed, and amputation of the thigh was performed, but the patient died shortly afterwards. The second case was that of a woman, aged 20, who in the course of two and a half years developed a slowly growing

tumour in one knee, which was diagnosed as tuberculous arthritis and treated first with plaster bandages and after wards by resection of the joint. The synovial membrane was reddish brown and thickened and the joint cartilages destroyed. Microscopically the synovial membrane presented the appearance of a pigmented giant celled xantho fibrosarcoma. There was no recurrence. (2) Circumscribed tumours in the joint. These are usually sarcomata. Habitz had previously described eight examples, and now records another in a patient, aged 58, in whom the growth—a calcareous fibroma—had lasted thirty years. In conclusion, he describes a case of primary giant cell sarcoma of the patella, a comparatively benign growth, in a man aged 49.

### 110 Leukaemia Simulating Malignant Disease

H VON SLEMMEN (*Munch med Woch*, May 27th, 1927, p 878) remarks that it is important for the surgeon to recognize the presence of leukaemia, in view of the fact that excision of an enlarged leukaemic spleen or lymphatic gland is indicated only in very exceptional circumstances, and that an operation of any kind in leukaemia should be avoided owing to the tendency to haemorrhage and the danger of aggravating the disease. He records three cases of leukaemia, which were admitted in the course of a year to the surgical clinic of Freiburg University with the diagnosis of malignant growth (gastric carcinoma, rectal carcinoma, and hypernephroma), in patients aged 58, 61, and 65 respectively, and adds that in order to avoid erroneous diagnosis of this kind it is advisable to make a careful examination of the blood before operation.

### 111 Unilateral Nephritis

B N KHOLTZOW (*Arch des mal des Reins et des organes genito urinaires*, April 1st, 1927, p 538) considers that the good results obtained by operation in surgical affections of the kidney is in great measure due to the fact that these affections are generally limited to one kidney. The previously accepted statement that "therapeutic" nephritis is always bilateral is now open to doubt, and it is admitted that cases may be unilateral, at least at the commencement of the disease. Whereas cases have been reported of unilateral urogenital and haematogenous infective nephritis, the toxic nephritis caused by poisons and microbial toxins is always bilateral. The fact that in cases of chronic nephritis both kidneys at the necropsy are always found to be involved does not exclude the possibility of unilateral infection at the commencement of the disease, and frequently one kidney is more affected than the other. Clinically it is not possible to decide with certainty the unilateral character of a "therapeutic" nephritis, but the author believes that in those cases associated with pain and haematuria, where nothing abnormal can be found in the urine and in the function of one kidney, there is a strong probability that the affection is unilateral. He gives details of three cases in which he removed the infected kidney, with complete cessation of symptoms and recovery of the patient. The diagnosis in each case was confirmed by the pathological report of the kidney removed. His observations also indicated that the view that haematuria occurs only in cases of isolated glomerular nephritis is not correct, since in one of his cases there was a generalized glomerular inflammation, and in another the kidney was small and atrophied. Koltzow discusses the advantages of nephrotomy and nephrectomy, and concludes that removal of the organ should always be practised in unilateral infection, since it is known that infection of one kidney will sooner or later extend to the other, possibly by the action of nephrotoxins or nephrolysis, which are developed, nephrectomy may therefore be regarded as a prophylactic measure.

### 112 Operative Treatment of Splenomegaly

R GREGOIRE and P L VILLI WIL (*Bull et Mem Soc Nat de Chin*, July 2nd, 1927, p 935) remark that removal of the spleen in cases of its primary enlargement has given varying results in the hands of different surgeons. In certain cases it is not wise to operate—for example, in cases of splenomegaly associated with leukaemia the condition is usually found to be myeloid leukaemia, and an examination of the blood at once shows their unsuitability for surgical treatment. Radiotherapy, however, gives some good results. In these patients, again, in Hodgkin's disease, where the splenic enlargement is associated with swelling of the glands, operation is contra-indicated. In certain other cases the splenic enlargement is due to a definite cause, being in the nature of a chronic inflammatory condition which may be due to syphilis, or parasitic, following infection by bilharzia or other organisms. These may give rise to vascular complications causing haemorrhages and anaemia, and later infections of the liver and ascites. Splenectomy at the right time may cure the condition. The chief indications for operation are enlargement of the spleen associated with anaemia and haemorrhages, when the disease does not respond to medical treatment. Operation is contra-indicated when there is evidence

of serious involvement of the liver function. This is shown not only by the size of the liver itself but also by the presence of jaundice and ascites. Operation under such conditions is not advised. The state of the patient can be improved, however, in selected cases by transfusions of blood and the use of insulin; the authors find that blood transfusion definitely inhibits the haemorrhages in a tumour in the manner splenic metastasis is in itself progressive and usually fatal and removal of the spleen in selected cases at the right time may cure the patient.

#### 112 Epilepsy following Cerebral Abscess

J. PONS (*Revue de Laryngologie*, April 30th 1927, p. 276) reports the case of a man, aged 21, who following an old meningitis, showed symptoms of cerebral complication. A radical mastoid operation was performed and two days later the temporo-sphenoidal lobe was explored and an abscess evacuated. Improvement occurred for a time and symptoms were removed after two weeks, but a second exploration revealed a pocketing of pus in the brain. A further increase of symptoms led to trichinosis of the temporal region and a superficial abscess was discovered and evacuated from that point all well and the wound healed but about a month after complete healing, epileptic fits of a generalized type began and continued at the rate of about five or six a year. Pons remarks that while such epileptic attacks are fairly common after injuries to the skull and brain they are comparatively rare after abscesses. It is not surprising that after an abscess with its surrounding inflammatory processes, there should be some cicatricial tissue in the brain and meninges which might give rise to epileptic attacks. In a case of localized epilepsy, exploration and separation of adhesions might be useful but in a generalized type it has proved to be useless. Leriche considers that vasomotor changes play some part in producing the epileptic state and has suggested in cases of hypotension infusion of a hypertonic glucose saline while in other cases he has suggested and employed carotid sympathectomy.

#### 113 Pseudo Peritonitis in a Diabetic Patient

W. USABEL (*Zentralblatt für Chirurgie*, May 23rd 1927, p. 1564) describes the case of a man, aged 26, admitted as a case of perforated gastric ulcer. He had had a sudden attack of severe abdominal pain twelve hours previously but without vomiting. He was pale and poorly nourished, there was a strong odour of acetone in the breath, and the urine contained much sugar and acetone but no diacetic acid. The abdomen was distended and very tense especially in the epigastric region but not very tender. The pulse was weak and rapid, and the temperature was 98.6°. As the condition suggested peritonitis from perforation of a gastric ulcer 100 units of insulin were injected and laparotomy was performed. No evidence of inflammation or of any visceral lesion was found so the wound was closed. The insulin treatment was continued and the wound healed by first intention. Three months after the operation the patient was well and had not had any recurrence of the pain. Although attacks of more or less severe abdominal pain are not uncommon in diabetic patients the author is not aware of any previous record of the occurrence of such severe symptoms simulating peritonitis. Ehrmann and Jacoby believe that these attacks of pain—"pancrealgia"—occur shortly before the advent of coma.

#### 115 Incidence of Malignant Disease in Java

T. WIEBERDINK (*Nederl. Tijdschr. v. Geneesk.*, April 30th 1927, p. 2334) states that while only a few data are available as to the occurrence of cancer in the Dutch Indies the general impression is that cancer occurs much more rarely in the native population than it does in European countries. In 1924 among 1,657 Europeans who died in the Dutch Indies there were 95, or 5.9 per cent, whose deaths were due to cancer as compared with 10 per cent in Holland. In the same year 121,347 patients almost exclusively natives were admitted to 171 hospitals in the Dutch Indies and among them were 582 or 0.48 per cent suffering from cancer. Of the 6,050 deaths in these hospitals 115 or 1.9 per cent, occurred among the cancer patients. Wieberdink however shows that a large number of cases of new growth are entered in the statistics under other headings. During thirteen months residence in Java he met with 175 tumours among 9,660 patients or about 2 per cent, which is about the same proportion as that in many European hospitals. Unlike the European statistics however in which cancers of the uterus and stomach together form about 50 per cent of the cases, Wieberdink's cases showed that these tumours were not specially frequent. Another remarkable feature was that the 113 cases of carcinoma of the rectum in his series were inoperable owing to their having been mistaken for dysentery, and treated with emetine or yatein without a digital or rectoscopic examination having been made.

## Therapeutics

#### 116 Non-operative Treatment of Enlarged Prostate

J. A. WEITLANDT (*Nederl. Tijdschr. v. Geneesk.*, June 11th, 1927, p. 322a) records a case of enlarged prostate in a man, aged 76 on whom operation was considered dangerous owing to the presence of pulmonary emboli and treatment by diathermy was employed. The case was specially suited for this method as there was only a local enlargement of the gland. The application of the high frequency current was facilitated by the use of Lewis's cysto-urethroscope and an excellent functional and anatomical result was obtained. The advantages of diathermy in the treatment of prostatic hypertrophy are given as follows: (1) the method is less radical and therefore less dangerous for the patient; (2) it can be performed quite painlessly by means of paracervical anaesthesia; (3) necrosis of the tissues can be produced without any risk of haemorrhage; (4) during the whole operation there is a clear view of what is being done. The method, however, is only suitable for cases with local enlargement, and in many cases it cannot take the place of prostatectomy. It must be borne in mind that rectal examination cannot give an accurate idea of the size of the enlargement round the neck of the bladder. This can be determined only by cystoscopic examination.

#### 117 Sodium Thio-sulphate in Arsenical Poisoning

T. D. HUGHES (*British Journal of Medicine*, April 9th 1927, p. 543) records a case of arsenical poisoning treated by the intravenous injection of sodium thio-sulphate. Arsenic was still present in the urine six months after the accidental swallowing of a single large dose but it disappeared there from with rapid clinical improvement when intravenous injections of sodium thio-sulphate were given. A man after eating potatoes boiled in water containing arsenic was seized with violent abdominal pain and purging, and was admitted to hospital in a collapsed state. Four days later dermatitis of the scrotum, hand and feet developed followed by extensive edema and motor disturbance with rigidity waxing. Sixteen intravenous injections of 0.75 gram of sodium thio-sulphate in 10 c.c. of water were given on alternate days and the urine was then found to be free from arsenic. The patient's clinical condition quickly became almost normal and there was no relapse. Pain disappeared after the tenth injection, he lost the abnormal tonic contractions, and became able to walk without a stick and to perform the finer movements with his fingers. While the first five injections caused no discomfort a reaction followed the others including acute sensory disturbances in the feet and accentuation of his general symptoms. Though alarming at first the reaction passed off in about twelve hours leaving the patient in a better state than prior to the injection.

#### 118 Blood Transfusion in Chronic Enterocolitis

G. C. WOOD and R. AIDIN (*Brit. Journ. Child Dis.*, April-June 1927, p. 107) remark that although for at least a decade transfusion of blood has been regarded as a valuable therapeutic measure in the treatment of distressing conditions in adults its value in the treatment of such infants has been appreciated only during the past few years—for example, in erysipelas, traumatic shock, post-operative shock, burns, acidosis, marasmus and acute intestinal intoxication. They record twelve cases of infants aged from 2 months to 2½ years suffering from chronic enterocolitis who were treated by blood transfusion with two recoveries. Their conclusions are as follows: (1) Blood transfusion is not a specific cure for chronic enterocolitis of infancy. (2) It is of no value when given to a moribund patient and must not be tried as a last resort. (3) It is most likely to be successful when the infant is over 9 months old. (4) It results in a temporary improvement of the digestive function in the majority of cases.

#### 119 Bismuth Thioglycolate in Syphilis

O. M. GRUNZEL, E. LYONS and P. PERKINS (*Brit. Journ. Child Dis.*, May 1927, p. 504) have tried to obtain a therapeutically active preparation of bismuth which would be soluble in water and so be more quickly absorbed. As the result of experiments they found that the tri-calcium salt of bismuth thioglycolate did not cause pain or local irritation and was non-cumulative and was deemed by spectrochemical analysis to be of one sixth of a gram in a 100 c.c. of intramuscular injection it had been absorbed and was distributed throughout the body. The authors have treated seventeen syphilitic patients with this preparation in 50 injections being given without pain, except on one occasion when the solution may have been introduced into or near a nerve trunk. No lumps developed except when injections were made into the arm, when they were small and only painful.

on pressuro. In one patient there was darkening of the gums showing that the bismuth had reached the degree of saturation. Gastro-intestinal disturbances did not occur, nor did albumin appear in the urine. Secondary and tertiary syphilitic lesions were rapidly improved, and the Wassermann reaction became negative in eight cases. The authors believe that the great advantage of this preparation is that it remains soluble in water, when injected into the body it does not form insoluble albuminates at the site of injections, and is not precipitated as metallic bismuth. It saturates patients rapidly without producing a cumulative toxic effect. To keep the patients in a saturated state the drug should be given three times a week, in doses of 1.3 mg per kilogram of body weight, or twice a week, in doses of 2 mg per kilogram.

#### 120 Peptone in Asthma and Hay Fever

P. VALLERY RADOT and P. BLAMOUXIER (*Bull et Mem Soc Med des Hop de Paris*, May 5th, 1927, p. 527) have treated successfully many patients suffering from hay fever, asthma, and spasmodic coryza by intradermic injections of concentrated peptone solution, their results in other conditions, such as urticaria, were inconclusive. Hay fever gave the highest percentage of successes, but the authors consider the treatment useless for prophylaxis, and state that it should be commenced only at the onset of the coryza and sneezing. The best results occurred among patients treated on the second or third day of the coryza, when a week had elapsed the results were less favourable. The injections were given daily for twenty days, improvement sometimes appeared at once, or between the twelfth and fifteenth doses, or after the last injection. A second course, commencing one or two weeks after the conclusion of the first, was occasionally required. In asthma the most favourable results were obtained in cases of pure spasmodic asthma without bronchial or pulmonary complications. The injections were often without effect in persistent asthma without intermissions, but its chronicity is not considered a contraindication, since patients who derived most benefit had suffered from asthma for many years. Peptone injections should be limited to patients who have frequent asthmatic attacks, they are not advised when the bouts are occasional only, and in spasmodic coryza the results are said to be very transitory. The authors use Witte's or Chassang's peptone, 50 grams being dissolved in sufficient distilled water to produce 100 c.c., the solution is deep brown and very viscid. It is placed in ampoules and sterilized at 115°C. The authors add that the whole of the injected fluid must pass into the thickness of the skin, pigmented areas may be produced if the peptone passes under the epidermis or hypodermically. The quantity of fluid injected should never exceed 3 to 10 c.c. Occasionally subcutaneous nodules remain at the site of the injections, but fomentations assist their absorption.

#### 121 Treatment of Epilepsy by Amyl Nitrite

A. POPEA and G. EUSTAZIOU (*Presse Med*, May 21st, 1927, p. 643) refer to the various theories—bulbar, cortical, and nuclear—which assign the epileptic attack to excitation phenomena of the central nervous system, and to others which explain the epileptic crisis as inhibition phenomena. It is known that cerebral anaemia provokes general convulsions and that stimulation of the cervical sympathetic, which produces cerebral anaemia by vaso constriction, is followed by convulsions as the result of the inhibition of the cortical centres. Arguing that if the epileptic crisis is a vaso constrictor effect it should be possible by means of some vaso dilator substance to suppress or at least to cut short the convulsive attack, they administered 3 to 5 drops of pure amyl nitrite by inhalation to sixteen different epileptic patients with the nature and sequence of whose attacks they were previously acquainted. To ten of these the drug was given during the convulsions, which were invariably arrested, after which there followed sweating, a short period of torpor and mental confusion, and a return to the condition usual between the attacks. In two cases the amyl nitrite was administered at the first appearance of the attack with the result that the slight convulsion ceased, the patient commenced to sweat, and quickly regained consciousness with only slight mental confusion. In one case the attack was in no way modified, except that the patient did not show the stage of excitement which usually followed his attacks. When the drug was inhaled during the period of excitement after an attack the excitement was only temporarily allayed, and when the inhalation was given during the stage of excitement preceding an attack the effect was only of short duration. From their observations of the modifications produced by the inhalation of amyl nitrite, either on the convulsive attack or on the psychic symptoms which accompany or follow the crises, the authors infer that the pathogenic basis of an epileptic attack should be regarded as a vaso constrictor phenomenon, and that the sympathetic system plays a definite and important part in the pathogenesis of epilepsy.

## Disease in Childhood.

### 122 Chest Examination in Children

J. H. MARCUS (*Med Journ and Record*, May, 1927, p. 618) emphasizes the importance of attention to detail in chest examination in children. Auscultation should precede percussion. The normal respiratory sound is broncho vesicular. Bronchial respiration is heard normally over a wider area at the root of the lungs in the back in infancy and early childhood than in later childhood and adult life. In infancy and up to late childhood the respiratory sound is the same at both apices, and the expiration is not prolonged at the right apex. If a weak respiratory sound suggests disease of the lungs the baby should be made to cry and thus to take a long breath. Pleural friction sounds are hardly ever heard in infants and young children, even though pleurisy may be present, in middle and late childhood, however, they are just as common as in adults. Light finger percussion should be the only form used, the percussion note is normally more resonant during infancy and childhood than later. A tympanic element is always added at the left base because of the position of the stomach, unless the organ contains food. The percussion note is not dulled at the right apex as in adults. A slight dullness over the manubrium due to the thymus may often be demonstrated, more intense sternal dullness is to be considered pathological.

### 123

#### Progeria

D. APERT and P. ROBIN (*Presse Med*, April 6th, 1927, p. 433) describe various clinical varieties and report a case of progeria, known also as the senile dwarfism of Viorot. According to Hastings Gilford, who in 1904 was the first to describe this morbid condition, the subjects of progeria, whether children or adolescents, present an aged and dwarfed appearance. The skin is dried, wrinkled, and resembles parchment, the blood vessels are very prominent and bare, the arteries are atheromatous, and the articulations, which are knotted, allow only limited movements. The patients cease to grow and rarely attain a height greater than 3 feet. Baldness is a characteristic, and many other slight abnormalities, such as alterations in the fingers and nails, are seen. From reported cases and their own observations the authors conclude that progeria is a well defined morbid entity presenting certain symptomatic variations. The absence of hair and down is not a necessary symptom, many patients having an abundant hairy growth. Subcutaneous fat is not lacking, and may be more or less conserved. The cranium, until adolescence is reached, presents lacunae, which are especially numerous along the sagittal suture or at the fontanelles. These lacunae fill in later owing to the formation of Wormian bones. The distention of the phalanges and shortening and atrophy of the nails are important diagnostic points. The skin is always altered, and often shows warty proliferations, liable to calcification. The great articulations are sometimes affected, and the feet are often exaggeratedly flat. Fractures, spontaneous or caused by the slightest injury, are liable to occur. The alveolar arcades are misplaced, as is by compression, and the teeth, particularly the incisors and canines, are badly arranged. The etiology and pathology of this disease have not been established, and no prophylactic or specific treatment is as yet known.

### 124

#### The Anaemias of Infants

LESNÉ and LANGLE (*Le Nouvellon*, March, 1927, p. 65) group the anaemias of infancy as follows: (1) Simple anaemia appearing from the second to the fourth month, almost invariably in premature infants. The red blood corpuscles are reduced to about three million per c.c.m., with the haemoglobin index remaining at about one. The prognosis is good. (2) Chlorotic anaemia occurs from the eighth to the twelfth month. The red blood corpuscles are practically unaffected in numbers, while the haemoglobin index falls very low—20 to 40 per cent. It is a common condition, as seen in premature infants, in twins, and especially in premature twins, in this last case the combination should always suggest syphilis. There is a marked diminution of the iron content. (3) Pseudo-leukemia (von Jaksch) develops from the sixth to the fifteenth month, particularly in girls. It is indicated by pallor, weakness, enlargement of the liver and spleen, particularly the latter, and haemorrhages towards the termination. Death occurs in a few weeks from cachexia or some intercurrent malady. The erythrocytes are reduced to about 1,500,000 per c.c.m., with a haemoglobin index of 50 to 25 per cent. The leucocytes range from 20,000 to 120,000 per c.c.m., but are generally around 30,000. In the commonest type myelocytes appear in large numbers, 6 to 27 per cent. Less frequently there is a lymphocytosis, a third form cosmophil cells are prominent, 8 per cent being polynuclears, and 2 per cent myelocytes. A fourth form in which lymphocytes and myelocytes appear in equal numbers

has been described. A necropsy shows an intense myeloid reaction of all the haemopoietic organs particularly those forming the red cells. (4) Leukaemic aencha is rare, the plastic dysplastic, and aplastic forms are described. This condition is rapidly fatal. (5) Leucemia is also rare, and generally occurs acutely with an increase of embryonic or undifferentiated cells 100 000 to 300 000. As regards etiology, the authors consider that the causative factors are syphilis, digestive disturbances particularly a deprivation of iron owing to too prolonged feeding on cow's or goat's milk rickets, tuberculosis, zymotic disease, prolonged suppuration, malaria, kala-azar, helminthiasis, and neoplasms and haemorrhage. In the treatment of these cases the authors emphasize the importance of (1) antisyphilitic measures when there is any evidence of specific infection. (2) correction of faulty feeding, the diet should be rich in iron, vitamins and albumin from the seventh month fruitaceous foods, vegetables especially spinach which is rich in iron, egg yolk, meat juice, etc. should gradually be added to the feeds and the quantity of milk reduced. (3) antirachitic regime, the maximum of sunlight and fresh air and small doses of cod liver oil. (4) exhibition of iron and of arsenic in the form of proteolytic iron in doses of  $\frac{1}{2}$  to 3 grains and of Fowler's solution 2 drops daily per year of age. Other remedies mentioned are benzol 5 to 15 drops a day—a cure has been reported. X-rays any improvement is only slight and temporary. Splenectomy cannot be attempted in infants. Of great value is the transfusion of blood from a suitable donor, mixed with 10 per cent sodium citrate solution in the proportion of 1 part of citrate to 9 parts of blood. This may be injected into two longitudinal sinuses into a vein at the bend of the elbow, subcutaneously or intraperitoneally. The authors have had good results even from injecting non-citrated blood rapidly under the skin though an ecchymosis often slow in absorption is thus formed. Ultra-violet radiation is said to be of particular value in the lighter cases which are rapidly cured, and even more marked anaemias are very often improved. The pseudo-leukaemic cases are unfortunately unaffected.

## Obstetrics and Gynaecology.

### 125. Differential Diagnosis of Ectopic Pregnancy

W. T. DUNFELTER (*Journal Amer Med Assoc*, April 23rd 1927, p. 1302) recognizes six varieties of ectopic pregnancy, each of which he represents diagrammatically so as to define the characteristic clinical signs which enable a differential diagnosis to be reached. In each diagram the average pulse rate and blood pressure figures are compared and thus such conditions as an early ruptured abdominal pregnancy can be contrasted with a late tubal abortion. His six groups are: early tubal abortion (pulse 80 blood pressure 110); late tubal abortion with repeated haemorrhages from the fibrinated end (pulse 120 blood pressure 80); sudden intraperitoneal tubal rupture (pulse 150 blood pressure 50); cases in which the tube ruptures between the layers of the broad ligament (pulse 120 blood pressure 90); formation of the gestation sac in the cornu of the uterus (pulse 90 blood pressure 100); and type in which the embryo escapes from the tube without causing much haemorrhage remains viable and becomes attached to the peritoneal surface (pulse 80 blood pressure 110). Dunfelter states briefly the treatment in these respective groups.

### 126. Treatment of Miscarriage due to Uterine Fibroids

R. LEIBOVICI (*Presse Med*, May 14th 1927, p. 613) draws attention to the frequency of fibroid growths as a cause of miscarriage and comments on the dangers produced by this condition. Complicating features are introduced into the process of expelling the foetus and the placenta with consequent risk of infection and interference with the blood supply of the tumour. Curetting may give rise to serious haemorrhage or infection, and the author describes a case of submucous fibroid in which this operation employed after abortion provoked such abundant and continued loss of blood that hysterectomy became necessary. He also mentions two cases in which the curetting was delayed by such pronounced sepsis as to necessitate hysterectomy. He suggests the following lines of treatment in the case of pregnancy in a fibroid uterus. If miscarriage is just commencing a temporizing policy will be the safest with careful watch for excessive haemorrhage or the incidence of sepsis. If there is serious bleeding, hysterectomy is generally a safer procedure than curetting, except, perhaps, in the case of a young woman when the latter operation and tamponade may be tried though preparations should be made for hysterectomy in case it becomes necessary. With suppuration

occurring in a fibromatous uterus hysterectomy will also be required since vaginal myomectomy is both difficult and often disastrous in these cases. The author recommends total abdominal hysterectomy with vaginal drainage. Vaginal hysterectomy will seldom be found to be practicable.

### 127

#### Ovarian Haemorrhage

G. STRAUCH (*Zentralbl. f. Chir.*, April 30th, 1927, p. 1103) disputes the view that in cases of haemorrhage from a ruptured ovarian follicle the loss of blood is usually slight. He states that numerous examples of severe and even fatal haemorrhage have been reported and in many cases the symptoms have resembled those of appendicitis. Strauch operated recently on a nullipara aged 27, who had been married three years; menstruation commenced two days before admission. Appendicitis had been diagnosed and there was severe pain on pressure in the right iliac fossa. The rectal temperature was 100.5°. On opening the abdomen the appendix was found to be healthy, but eighteen ounces of coagulated blood were present in the peritoneal cavity. In the right ovary there was a laceration more than half an inch in length; this was sutured and the patient recovered.

### 128

#### Myo hysteropexy

UNDER this term JACOBOWICZ (*La Gynecol.*, April 1927, p. 212) describes an operation for complete uterine prolapse. The normal uterus is very mobile and when excessive mobility is replaced by an absolute immobility the change tends to give it a trouble. In his operation the author keeps the uterus in place by reconstructing the means of suspension and support the former being by means of the ligaments and the latter the pelvic floor vascular pedicle and the parametric tissues. Two variations of the operation are described in one, the psoas muscles and in the other the intra-abdominal muscles are utilized. In the former laparotomy is first performed. The parietal peritoneum is then incised at the aortic bifurcation prolonging the length of the psoas as far as the iliac artery towards the bottom of the retro-vesical pouch. The bladder and uterus are separated up to the insertion of the vagina and the peritoneum from the iliac fossa. The psoas minor muscles are cut at their lower insertions and detached as far as their upper ones. The ends are fixed by a U shaped suture to the anterior surface of the cervix immediately above the insertion of the vagina. The peritoneum and parietal walls are then closed. In the second procedure, after laparotomy and separation of the bladder and uterus a section of a bundle of the right muscles 2 cm wide and 10 cm long is made and the bundle freed to its pubic insertion. Two openings are made in the parametrium above the uterine arteries through which the free ends of the muscles are passed and fixed by a U formed suture the one to the posterior and the other to the anterior surface of the cervix. The uterus is then replaced and the wound closed. The patient should remain in bed for fifteen days. The author states that by this operation the uterus is restored to its normal site, pregnancy is uncomplicated and labor is normal. The advantages of the method are the preservation of uterine mobility and the utilization of fasciculi composed of tendons, muscles and aponeuroses the vitality of which ensures retention of the uterus in the correct position.

### 129

#### Basal Metabolism in Pregnancy

ACCORDING to A. PERALTA RAMOS and M. SCHTEINGART (*Gynecol. et Obstet.*, May 1927, p. 333) experimental research and clinical observation show that the thyroid gland influences both mother and child during pregnancy while conception cannot occur unless the thyroid shows some degree of activity. If hypothyroidism does not prevent conception the consequent oedema of the uterine mucosa interferes with the fixation of the ovum. During pregnancy thyroid hypothyroidism is almost always present and symptoms of hyperthyroidism may occur. The authors tried to determine the heat production of pregnant women at the different periods of gestation and how the thyroid responds to the physiological demands of pregnancy. In 61 per cent of their cases basal metabolism was increased, as shown by augmented heat production especially during the latter stages of pregnancy, though the cause of this increase was no altogether clear. The authors remark that pregnancy is a complex process which makes great demands on the maternal organism and particularly upon the endocrine system. The thyroid controls the heat output of the whole organism; it is the predominant although not the sole factor in the increase of basal metabolism. Among women who show signs of slight hypothyroidism under normal conditions this deficiency may be compensated during pregnancy by increased activity of the other endocrine glands giving an apparently normal basal metabolic rate if taken alone but indicating an increased metabolism by comparison with the same patient's index when non-pregnant. This appears to be the explanation of

the normal metabolic index in some cases during the later period of pregnancy. It is probable that the reduction in the quantity of protein prescribed for many patients towards the end of pregnancy helps to lower the index in these cases. The increased heat output is a physiological necessity which should balance the energy dissipated in the processes of foetal development.

### 130 Severe Ovarian Haemorrhage Simulating Acute Appendicitis

O THOMANN (*Zentralbl f Chir*, May 21st, 1927, p 1297) reports a case of haemorrhage into the ovary which gave rise to the symptoms of appendicitis. A previously healthy woman, aged 20, had a sudden attack of violent pain in the right inguinal region, followed by repeated vomiting. The previous menstrual period had occurred three weeks earlier and was normal in all respects. The patient complained of pain on pressure a fingerbreadth below McBurney's point. There was definite muscular rigidity in the right lower quadrant, but otherwise the abdominal wall was soft. The right adnexa could not be palpated on account of this rigidity, and no abnormality was found. Under the impression that this was a case of acute appendicitis the abdomen was opened five hours later. It contained about 26 ounces of blood that had escaped from the right ovary, which was as large as a walnut and was ruptured longitudinally, it resembled a sponge filled with blood—the characteristic appearance of an ovarian haematoma. The bleeding appeared to have been arrested spontaneously. The appendix and left ovary were apparently healthy. The differential diagnosis lay between ovarian pregnancy and haemorrhage from a ruptured follicle. In view of its uncertainty and the possibility of a subsequent recurrence of the haemorrhage, the right ovary was removed and appendicectomy was performed. The patient made an untroubled recovery, and two days after the operation a normal menstrual period began. The pathological examination showed very hyperaemic but otherwise normal ovarian tissue penetrated by a broad band of haemorrhagic clots in the organ. It appeared to be a case of "interstitial haemorrhage" (ovarian haematoma).

## Pathology.

### 131 Etiology of Tuberculosis of the Thoracic Wall

FROM the study of a number of cases in which infection of the thoracic wall occurred in a patient with other tuberculous lesions, G SIMON concludes (*Med Klinik*, May 20th, 1927, p 753) that though tuberculosis of the ribs is generally haematogenous in origin, tuberculous periostitis and osteitis may arise by direct spread from the lungs and pleura, since in a quarter to one third of the cases of tuberculous rib there is evidence of an old localized pulmonary focus, generally of the fibrotic type. Intrathoracic foci were found to be much more frequently associated with tuberculosis of ribs than with tuberculosis of other bones. Simon also considers that direct spread of infection accounts for the well recognized fact that the average age of patients with rib tuberculosis is higher than that of patients with other tuberculous bony lesions. In one case the continuity between a fistula from a carious rib and a pulmonary lesion was accidentally discovered when cough and unpleasant taste resulted while the fistula was being treated with injections of Calot's paste. The connection was subsequently demonstrated radiographically with iodopin. The possible continuity between a tuberculous lesion in the thoracic wall and an intrathoracic focus is of special importance when surgical treatment is contemplated.

### 132 Factors Influencing the Growth of Anaerobic Organisms

G M DICK, W A STARR, and MARIE WELFNER (*Journ Infect Dis*, April, 1927, p 525) have endeavoured to ascertain why the growth of certain anaerobic bacteria is so irregular. It is known, for example, that the spores of *Cl botulinum* may not germinate for weeks or months in apparently suitable culture media, and that in any batch of canned food only a single can may contain the toxin of this organism. It is clear that the application of heat, the hydrogen ion concentration of the medium, the amount of inoculum, and other factors play a part in this delayed germination. The authors have now investigated the effect of varying the atmosphere in which the organisms were grown. The procedure was to plant a known number of vegetative bacilli or of spores into veal broth contained in constricted test tubes. The air over the medium was evacuated to various pressures, or replaced with oxygen or carbon dioxide under low pressures. The tubes were then sealed, incubated, and watched for the pro-

duction of turbidity. The organisms used were *Cl botulinum*, Types A and B, and *Cl sporogenes*. The actual cells used for the inoculum were washed with saline solution to free them from toxin, spores were heated, in addition, to 80°C for ten minutes. The results showed that growth occurred within two days when the air pressure was reduced to 4 cm of mercury or lower, above this pressure growth was irregular, sometimes not occurring for sixty or seventy five days, at pressures higher than 16 cm no growth occurred at all. When the air was replaced by oxygen at pressures of 5 and 10 cm there was no growth, even after three months. But in atmospheres of carbon dioxide at pressures ranging from 5 to 50 cm growth occurred uniformly within two, or at the latest three, days. The production of toxin was estimated by the intraperitoneal injection of mice after the cultures were one, five, and thirty days old. The maximum production of toxin was found in the five day cultures, the titre appeared to be slightly higher in those tubes incubated under carbon dioxide than in those under air at low pressure. The authors conclude that the degree of anaerobiosis is at least one factor influencing the delayed germination of *botulinum* spores.

### 133. Histogenesis of Bronchial Carcinoma

F FEARTER (*Wien klin Woch*, May 19th, 1927, p 648) has endeavoured to determine whether the bronchiectasis and chronic pneumonic changes so often found at the periphery of bronchial tumours are secondary or primary, and if they result from stenosis by bronchial growth, or whether the cancer originates in a chronic bronchitic or pneumonic lesion. To this end he has, in four cases of squamous celled carcinoma of the bronchi, made systematic examination of the entire bronchial system, noting the nature of the growth and characters of the epithelial cells. He found at a great number of places, in bronchioles far removed from the malignant tumour, extensive pillings up of the epithelium, papillary growths of the mucous membrane, frequently atypical epithelial growths, and in one case an early carcinoma, only detected microscopically, in this case also two independent carcinomatous areas in the bronchial tubes had been recognized macroscopically. The author considers that every chronic inflammatory irritation of the bronchial mucous membrane can be regarded as a factor in originating carcinoma of the bronchial system, he associates the extensive and severe metaplasia of the bronchial epithelium noticeable in influenza infected lungs with the remarkable increase of bronchial cancer which occurred in the years following the great influenza epidemic of 1918-19.

### 134 Streptococcal Toxins and the Dick Reaction

E SACQUÉPÉE and P LESBRE (*C R Soc de Biologie*, June 17th, 1927, p 27) bring evidence to show that there is a close similarity between the toxins secreted by haemolytic streptococci. They isolated twenty six strains of these organisms from non scarlatinal suppurative and septicemic affections, and prepared toxins from them according to the method recommended by the Dicks. Intradermal tests on human beings were then made, using as a control the same toxin boiled for one hour. No fewer than nine of these strains proved active in a dilution of 1 in 500 or over, the titre of all of them was not ascertained, but the strongest toxin was active up to a dilution of 1 in 1,200. Of the other strains the majority were active between 1 in 50 and 1 in 500, a few were non toxic. Nine strains of streptococci of scarlatinal origin were similarly tested, six of these were active at 1 in 500 or over, the most active reaching a titre of 1 in 2,000. The reactions evoked by the non scarlatinal toxins were comparable to those seen in the ordinary Dick test, especially in their aspect and in the time of their appearance, duration, and disappearance. The non scarlatinal strains which secreted the most active toxins generally came from severe cases of infection, such as acute mastoiditis, septicæmia, and infectious phlegmons. On the other hand, the strains isolated from two chronic relapsing infections proved to be non toxic. As a general rule the reactions of normal persons to the toxins of the scarlatinal and the non scarlatinal groups were similar—that is to say, a person who reacted to the toxin of one group likewise reacted to the toxin of the other. It was also found that in the Dick reaction it was often possible to replace the specific toxin by the toxin of a non scarlatinal streptococcus. Patients suffering from non scarlatinal streptococcal infections often gave positive intradermal reactions to toxin at the beginning and during the course of the disease, followed by negative reactions during convalescence. In some of these patients the non scarlatinal could be replaced by the scarlatinal toxin without altering the results of the test. The authors conclude that in streptococcal infectious there does not appear to be any essential fundamental difference between the skin reactions evoked by the toxins of streptococci of scarlatinal and those of other origin.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine

### 135. Clinical Value of the Dick Test

J C J MCENTEE (*Iris Jour. Child Dis.*, April-June, 1927, p 91) carried out the Dick test in 520 cases, which consisted of 265 cases of definite scarlet fever, 23 cases of clinically doubtful scarlet fever, 193 diphtheria patients who had not had scarlet fever, 13 nurses and 20 medical students. The percentage of positive reactions from the first to the fourth day of scarlet fever was 73.6, from the fifth to the seventh day 40, from the eighth to the seventeenth day 33.1 from the eighteenth to the thirty first day 25.1 and from the thirty second day and later 15.7. The number of positive reactions thus showed a steady fall corresponding to the production of antitoxin during the course of scarlet fever. As many as 50.2 per cent of the diphtheria cases gave a positive reaction, thus confirming the well known susceptibility of diphtheria patients to scarlet fever. McEntee's conclusions are as follows: (1) A Dick negative reaction indicates a high degree of immunity to scarlet fever. (2) A Dick positive reaction is evidence of lack of circulatory antitoxin but does not necessarily denote susceptibility to scarlet fever. (3) A polyvalent toxin would give a more reliable indication of susceptibility. (4) Because it is not reliable the Dick test though helpful, is not alone a guide to diagnosis. (5) The skin reaction is not proportional to the amount of toxin injected. (6) A different and more accurate means of standardizing scarlatinal toxin must be devised.

### 136. Recovery from Addison's Disease

J L A PEUTZ (*Vierteljahrsschr. f. Geneesl.*, June 18th, 1927, p 3295) records a case of Addison's disease in a boy, aged 12, who belonged to a family of eleven children, two of whom had died of tuberculosis and one was in hospital with a pleural effusion, while the mother was the subject of chronic bronchitis. In addition to extensive areas of pigmentation of the trunk, extremities and buccal and rectal mucous membranes, the patient showed a general muscular tonelessness and apathy. The systolic blood pressure taken on several occasions with Riva Rocci's sphygmomanometer, ranged between 70 and 80 mm Hg. The bowels were constipated and only acted after administration of castor oil. Treatment consisted in subcutaneous injections of half a milligram of adrenaline once daily and arsenious acid twice daily, and strychnine and quinine by the mouth. He was also given fresh suprarenal substance twice a day. The patient was kept under observation for eight years and made a complete recovery.

### 137. Infectious Mononucleosis

E T F RICHARDS (*Minnesota Med.* July 1927 p 34) reports four cases of mononucleosis and contrasts the clinical picture of this condition with a case of simple lymphocytosis with adenitis and a case of acute lymphatic leukaemia. He thinks infectious mononucleosis is a distinct clinical entity characterized by adenopathy, splenic enlargement, fever and leucocytosis of pronounced lymphocytic type. The lymphocytes being relatively and absolutely increased in number and associated with the presence in the circulating blood of abnormal mononuclear lymphoid cells. These cells, which are regarded as peculiar to this condition and which do not occur in the healthy blood in the blood of simple lymphocytosis with adenitis, or in the blood of lymphatic leukaemia, are larger than the normal lymphocyte having deeply basophilic often vacuolated, cytoplasm in which a coarsely reticulated usually indented or lobulated nucleus is situated often eccentrically. The finding of these abnormal lymphoid cells, which dominate the blood picture and the fact that in infectious mononucleosis runs a benign course terminating in recovery are regarded by the author as the chief features which distinguish the condition from lymphatic leukaemia, although in the early stages of the illness there are many points of resemblance.

### 138. Epidemic Meningitis in Early Infancy

J B NEAL and H W JACKSON (*Journ. Am. Med. Ass.*, April 23rd 1927 p 1239) record their observations on 5 cases of epidemic meningitis during the first three months of life which they had seen in the course of the last sixteen years in New York City. Of these, 25 were due to the meningococcus 11 to the streptococcus, 7 to the pneumococcus, 5 to the tubercle bacillus, 3 to B. coli and 1 to

*Micrococcus catarrhalis*. The symptoms of meningitis in infancy, whatever the causal organism may be, are quite different from those in older children and in adults. The onset is fully acute, but rarely so sudden as in later life. The disease is practically always ushered in with a disturbance of the gastro intestinal tract and irregular fever. The child is usually irritable and hyperaesthetic. Convulsions may appear early, but are not so severe as those which occur later. The typical symptoms of meningitis, such as rigidity of the neck and Kernig's sign, are usually absent until the disease is far advanced. The reflexes at the beginning are usually normal. A bulging fontanelle is nearly always present. A haemorrhagic rash is very unusual. In the meningococcal cases daily lumbar puncture was performed and as much fluid as possible was removed. If 20 cc or more of fluid was obtained the same quantity of serum was injected, and the injections were repeated daily as long as organisms were present in the spinal fluid. Even after the fluid became sterile the injections were continued if the clinical condition required it. Ventricular or cisternal puncture was performed if there were definite signs of blocking. Of 23 patients treated by serum 11 died, a mortality of 47.8 per cent. This was higher than the mortality among the authors' cases during the first year of life (46 per cent) and far above that during the second year (29.2 per cent). Sequels were very few. Of 11 patients who could be followed up 1 was deaf and the other 10 made a complete recovery.

## Surgery.

### 139. Etiology of Pulmonary Cancer

E FROMMEL (*Rev. de Med.* No 1, 1927 p 31) states that from 1900 to the end of September, 1925, 41 cases of pulmonary cancer in which the diagnosis was verified after death were admitted to the medical clinic of Geneva University. Of these 40 were examples of carcinoma and 1 of sarcoma of the Schneeberger type. 30 occurred in men and 11 in women. The ages of the patients ranged from 27 to 91 years, the average being 58. Frommel concludes therefore that cancer of the lungs is an affection of the second half of life, the male sex being principally affected. Among 40 cases in which the history could be elicited 30 patients had suffered from other lung affections before cancer developed. Pulmonary tuberculosis had been present in 8 cases, in 6 of which it was found in the same lobe as the cancer, thus showing that the two processes are not incompatible with one another, as Pottansky maintained. Frommel adds that there is evidence, on the other hand, that pulmonary tuberculosis acts as a chronic irritant and favours the development of cancer. Chronic bronchitis, bronchiectasis, emphysema was present in 22 patients, so that their lungs were in a condition of diminished resistance. The part played by dust in the precancerous state is illustrated by the fact that out of 29 engaged in a definite occupation 22 were exposed to the inhalation of material or vegetable dust.

### 140. The Dangers of Abdominal Puncture

F PAPTSCH (*Zentralbl. f. Chir.* July 9th, 1927 p 1755), referring to the discussion on diagnostic abdominal puncture at the Berlin Surgical Congress in April when Frangenheim recommended the use of Goetze's needle with safety stilette in order to avoid injury to abdominal viscera, states that its employment is contraindicated in acute inflammatory conditions. Papsch believes that the principal danger lies in abnormal relations of the intestine and he maintains that artificial pneumo-peritoneum should be employed only as a supplementary diagnostic method when all others have failed. He describes the case of a man in whom a hydatid cyst of the liver was suspected. In order to confirm the diagnosis and to determine the position of the cyst and the most suitable operative route, an artificial pneumo-peritoneum was performed. A Goetze's needle being inserted in the mid line between the umbilicus and pubis and the introduction of an being observed under the fluorescent screen. The needle appeared to be freely mobile in the abdominal cavity. After the introduction of a very small quantity of air the patient complained of intense abdominal pain, he became cyanosed and dyspnoic and died suddenly. The necropsy revealed an embolism and an entirely abnormal position of the liver, its greatly thinned and compressed lower border was only three fingerbreadths above the pubis. A most careful abdominal palpation had failed to show this

were the symptoms as severe as the frequently medicated by epinephrine. In his fever it was found that oral administration had advantages over local application to the nose. In asthma the best results were obtained in the allergic and reflex cases (84 and 100 per cent. respectively) and in addition to producing bronchial dilatation the oral administration of epinephrine caused contraction of the nasal mucous membrane.

#### 135. Protein Therapy in General Paralysis

W. B. JENNINGS (*Med. Journ. and Hosp. June 10th 1927* p. 793), from a clinical study of the treatment of general paralysis by intravenous injections of foreign protein in 13 cases, supports Prof. Kunkel's previous findings. In 12 cases treated intravenously with a solution of typhoid vaccine that the method appears to be as variable as the malarial treatment without involving any danger. Colloidal albumin with an initial dose of 2.0 to 3.0 ml. though with each succeeding dose was increased until the patient had had twelve to fourteen injections. A continuous reaction followed in most half an hour with a rise in temperature reaching its maximum about three hours later and accompanied by a chill varying from a slight sensation of cold to a marked rigor. With one exception the temperature became normal in four to eight hours after the fist injection was reached. The average time for the entire reaction being from ten to twelve hours. As in the malarial treatment a favourable serological influence was noted the cell count improved. But the global second Wassermann reaction third and finally the gold reaction but a dissimilarity between the two methods was seen in that a marked leucocytosis occurred in the protein treatment. After three or four injections mental and physical improvement was noted as evidenced by a more normal demeanour, increased interest in surroundings, improved memory, disappearance of tremor, speech defects and grandiose ideas and easily gained weight. Of the 13 patients treated 10 were greatly and 5 slightly improved while 3 showed no improvement. There were no deaths and with the exception of herpes labialis no complications. Jennings considers that with careful selection of patients to exclude cardio-renal disease as a contra-indication the method has many advantages over malarial treatment in which marked anaemic jaundice and a mortality of from 6 to 20 per cent. are serious complications. He advocates further study of the method as possessing distinct advantages over those in which living organisms are used.

## Ophthalmology

#### 137. Familial Maculo-cerebral Degeneration

S. J. BEACH (*Arch. Ophthalmol.*, May 1927 p. 225) describes two cases of the so-called maculo-cerebral degeneration which are unique in that the patients were children of the same mother but of different fathers. Moreover both fathers by other marriages had had normal issue. The cases were also atypical in that the vision began to be defective about the age of puberty, and in each case there were cerebral disturbances. True maculo-cerebral degeneration is divided into two types: (1) at about the period of the second dentition (6 to 7 years) failure of vision and intellect begins; (2) macular changes occurring at puberty (14 to 16 years) without mental deterioration. True maculo-cerebral degeneration is said to be familial but not hereditary. In the two cases mental and retinal deterioration started at puberty.

#### 138. Vaccine Therapy in Ophthalmology

M. TIGLIPES (*Journ. de Med. de Bordeaux* July 10th 1927 p. 569) discusses the different kinds of vaccines suitable for practice in ophthalmology, and their use in prophylaxis and treatment. He suggests that the eye is a suitable area for local immunization and has treated cataract cases in this way before operation with encouraging results. In ophthalmic tuberculosis he approves the use in cases of keratitis scleratitis, and infectious of the anterior part of the eye but not deeper infections especially where there are other tuberculous foci. In gonococcal infection the results were variable but success was obtained in refractory metastatic cases of iritis and iridocyclitis. Considerable benefit followed the employment of vaccines in staphylococcal infection of the lids and lashes. He prefers autogenous vaccine. In infectious due to pneumococci streptococci and staphylococci he has had good results where other means have failed particularly in cases of inflammation and abscess of the lacrimal sac, acute pseudo-membranous conjunctivitis severe keratitis hypopyon and post-operative cataract infection. The local reactions were never violent and in monovalent vaccines almost negligible, even in children. The general reactions

were usually been slight often imperceptible, with monovalent vaccine but with polyvalent vaccines there was much more they were never alarming, however. The author reserves vaccines for very grave cases where the loss of sight in one or both eyes or the organ itself is threatened.

#### 139. Treatment of Scar of the Cornea

S. R. GIFFORD and A. STEINBECK (*Amer. Journ. Ophthalmol.*, April 1927 p. 240) describe a method of colouring corneal scars by gold salt. Opaque white scars of the cornea are very unsightly, and when the scar is not absolutely opaque the light diffused through it will tend to cause a dazzle and in effect with the vision obtainable through the remaining transparent part of the cornea. For these two purposes various methods have been employed the best known being the tattooing of the corneal scars with Indian ink. The authors prefer to apply gold chloride solution to the corneal scar. The eye is anesthetized with 10 per cent. cocaine solution, and the area to be scarred is marked out superficially with a 3 mm. trephine. The epithelium over this area must be completely removed. An applicator dipped into the gold solution is applied to the scar repeatedly until the solution has been in contact with the cornea for four minutes, after which 5 to 10 drops of a 1 in 1,000 solution of adrenalin are dropped into the eye. In twenty-four hours the scar is black or dark brown in colour and the epithelium has grown over the scar in four or five days. The authors add that 4 and 5 per cent. solutions of gold chloride can be used and it is best to keep the solution very slightly acid.

## Obstetrics and Gynaecology

#### 150. Artificial Vagina

G. A. WAGNER (*Zentralbl. f. Gyn.*, May 21st 1927 p. 1300) has had very good end results in seven cases in which he has constructed an artificial vagina by Schuchert's method in which the large intestine is used. In one case described a very rather Wertheim's operation was performed in a patient aged 36 for extensive carcinoma of the cervix and vagina six years later there was no recurrence and the woman wished to marry but coitus was impossible. A small recto-vaginal fistula necessitated intervention nine days after operation but a satisfactory functional result was secured. In a second case a functioning uterus was present. The patient a married woman, aged 28 after a difficult labour three years previously had had incontinence of urine and faeces and cohabitation had been impossible. There was a circular ectoanal stenosis in the vagina with narrowing of the introitus and a recto-vaginal fistula. The patient, an orthodox Jewess demanded operative treatment in spite of its difficulty and danger. The vaginal remnants were excised the fistula was closed and repaired and sexual congress was thereafter accomplished without difficulty or pain. A third patient had a similar operation for vaginal scarring which impeded mensuration. In the second year following operation a living child was delivered by Caesarean section, and in the third and fourth years other living infants were delivered spontaneously *per vias naturales*.

#### 151. Treatment of Foetal Asphyxia

P. CASTAGNA (*Rev. d'Obst. et Gynecol. Prat.* April 1927 p. 14) records five cases of pallid foetal asphyxia treated successfully by subcutaneous injection of lobelin and states that fully by subcutaneous injection of lobelin and states that good results have also been reported at the Gieson, Monaco, and Novara clinics. The doses given have been from 1 to 6 mg. Castagna prescribes a dose of 2 mg. Lobelin is stated to act as a respiratory failure during general anaesthesia by increasing the number and amplitude of respirations. It may be advisable in foetal asphyxia to stimulate the heart by a preliminary intracardiac injection of adrenalin.

#### 152. Treatment of Post partum Haemorrhage

W. M. J. SCHLLENS (*Nederl. Tijdschr. v. Genees.*, May 21st 1927 p. 2851) states that several recent articles especially by German writers have drawn attention to the good effects of intravenous injection of pituitrin in severe post partum haemorrhage. Schellens has employed his method in twenty-two cases during the last three years. His conclusions being as follows:—In atonic haemorrhage following expulsion of the placenta when uterine massage combined with compression of the uterus fails to control the bleeding small doses of pituitrin (1/3 to 1/2 cm.) should be injected intravenously as a result the uterus usually contracts powerfully within half a minute. Directly after the intravenous injection of pituitrin he injects glycogen intramuscularly to prevent subsequent muscular relaxation. If the haemorrhage recurs the intravenous injection of pituitrin should be repeated.

cardiac, or vascular disease, or eclampsia are present the dangers of intravenous injection of pituitin should be borne in mind owing to the sudden rise of blood pressure caused by it. When attempts at intravenous injection fail the pituitin should be injected directly into the uterine muscle, this should also be done in Caesarean section. When intravenous injection of pituitin fails to control the hemorrhage the advisability of plugging the uterus and vagina should be considered.

**153 Intracranial Haemorrhage after Spontaneous Birth**  
VORON and PIGEAUD (*Bull. Soc. d'Obstet. et de Gynecol. de Paris*, April, 1927, p. 273) record three cases in which after spontaneous delivery the infants died within four days, intracranial haemorrhage, which had been diagnosed clinically, was also demonstrated at the necropsies. In one case the birth occurred six weeks before term, and in all delivery was rapid. The view is advanced that the meningeal hemorrhages were due not to birth trauma, but to maternal syphilis. In one case the Wassermann reaction was positive and in the other two the spleen and liver were enlarged and microscopic examination of the latter pointed to congenital lues. TRILLAT and GAUCHERAND (*ibid.*, p. 268) record the case of a puerpera, aged 29, with flattened and generally contracted rachitic pelvis, whose labour ended spontaneously, after seven hours, in the birth of an apparently vigorous infant weighing 7½ lb. On the first day the breast was refused, and on the second day a state of somnolence was noted which necessitated feeding by stomach tube. Cyanosis, contractures, and convulsions were absent, some emphysema followed lumbar puncture, which gave issue to an amber coloured fluid. Erythrocytes were noted in a second sample of cerebrospinal fluid drawn off three days later, after this recovery was swift.

## Pathology.

**154 The Origin of White Blood Cells**  
M. SILBERBERG (*Med. Klin.*, May 27th, 1927, p. 798) produced leucocytosis (granulocytosis) by poisoning rabbits with benzol. The myeloid tissue became aplastic, the capillaries being distended with endothelial cells, the leucocytes in the peripheral blood showed at first basophilic punctations, then broke up and disappeared, the lymphocytes were very few, though in marrow smears they showed a relative differential count of 75 per cent., the monocytes remained constant. Staphylococcal septicaemia was then induced in these rabbits and resulted in the production of numerous abscess-like formations in the heart, peripheral muscles, and kidney, which on microscopic examination were purely necrotic, with no proliferation or exudation, or any trace of cellular defence reaction. These animals died sooner than the control animals, some of which survived with healing of the abscesses. These observations demonstrate the importance of granular leucocytes as inflammatory cells, and that neither lymphocytes, monocytes, nor histiocytes can act as substitutes. The leucocytes are macrophages, the monocytes and histiocytes are macrophages, but the action of the lymphocytes is not as yet known. To determine whether the properties of the blood forming organs were impaired, *in vitro* cultures of myeloid and lymphatic tissue were made from the benzol-treated animals, these tissue cultures showed growth and extensions of lymphocytes, monocytes, histiocytes, and fibroblasts, but no growth of myeloid granular cells. When the cultures of histiocytes and monocytes were treated with charcoal particles vigorous phagocytosis was seen in these cells, demonstrating that their biological character as macrophages was not destroyed. The histiocytes and monocytes can be formed locally, but there was no evidence that this was possible with the granular leucocytes. This research indicates the prominent part taken by the mesenchyme germ layer in the defence against septic infections.

**155 Filterability of the Tubercle Bacillus**  
L. BERNARD and NELIS (*Presse Méd.*, June 8th, 1927, p. 721) discuss the recent work on the filterability of the tubercle bacillus. Lontes in Brazil first filtered dilute caseous pus through a Berkefeld candle, inoculated the filtrate into guinea pigs, and observed tumefaction of the inguinal glands in one of them. The spleen of this animal was inoculated into fresh guinea pigs, some of these developed pulmonary lesions containing typical acid fast bacilli. This observation has been repeated by several French workers. Valis inoculated 5 to 10 c.c. of a Chamberland L3 filtrate of antolysed

at the site of inoculation or in the focal glands, but some grew thicker and died in three or four months. At necropsy some of the lymphatic glands—chiefly the tracheo bronchial group—were swollen, there were also small areas of hepatisation in the lungs. Microscopically in these lesions it was possible to demonstrate a few acid fast bacilli. The conclusion is that tuberculous pus contains, besides the usual acid fast bacilli, certain invisible filterable forms, which on inoculation into guinea pigs give rise to an entirely different type of disease from that caused by the usual form of organism, it is characterized by the production of glandular swellings and the presence in the lesions of an extremely small number of typical acid fast bacilli. If filterable forms of tubercle bacilli are present in the blood of tuberculous women they should be capable of traversing the placenta and giving rise to infection in the foetus. Calmette and his colleagues have stated that by animal inoculation it is possible to demonstrate these filterable forms in the organs of newborn infants of tuberculous mothers dying shortly after birth. He also attributes a large part of the mortality of such infants during the first year of life to infection with this filterable form of bacillus. Boinard and Nelis object to this hypothesis on clinical grounds. They find that infants born of tuberculous mothers invariably give a negative skin reaction to tuberculin, if they were infected with a filterable form of the tubercle bacillus they should react positively for it is possible to sensitize animals to tuberculin by injection with filtrates of tubercle bacilli. They conclude that Calmette's thesis is not proven, and that contagion after birth, especially when familial, plays a preponderant part in the transmission of tuberculosis.

**156 A TOGUONNOIR** (*C. R. Soc. de Biologie*, July 8th, 1927, p. 349) filtered cultures of tubercle bacilli in liquid media through Chamberland L2 and L3 candles. The filtrates were planted on glycine agar and subcultured on Petroff's and Besicovich's egg media. They were also inoculated subcutaneously or intraperitoneally into guinea pigs, a dose of 2 to 10 c.c. being used, the animals which did not die of intercurrent disease were killed as a rule two to six months later. In the first series of experiments she examined the filtrates of eleven strains that grew freely in culture and were of low virulence. From one of the filtrates she obtained a positive culture of tubercle bacilli. None of the injected guinea pigs died. When they were killed they showed no specific lesions of the organs, some of them showed slight glandular enlargement. After a prolonged search she found a few acid fast bacilli in the glands of three of the animals. In the second series of experiments she examined the filtrates of fifteen virulent strains, most of which had been recently isolated from human patients. Cultures of these filtrates proved uniformly sterile. Of the injected guinea pigs four died of intercurrent disease. The remainder, when killed, showed slight glandular enlargement, especially of the tracheo bronchial glands, with increased areas in the lungs containing occasional epithelioid cells. The lungs of one animal contained definite tubercles. A prolonged search revealed the presence of acid fast bacilli, often very short, in the glands of six of the animals. The author concludes that filterable forms of both virulent and avirulent strains of tubercle bacilli may be present in cultures, but that they rarely give rise to specific nodular lesions when injected into guinea pigs.

**157 Experimental Cancer in White Mice**  
G. GULDBERG (*Norsk. Mag. f. Laegevid.*, June, 1927, p. 42) by painting white mice with tar produced epithelial tumours which, according to the duration of the painting, and the survival of the animals, showed a continuous series of development from papillomata with incipient histiocytic growth to fully developed carcinomata which invaded muscles, vessels, and nerves. In a series of experiments on 25 white mice there resulted altogether 1 papilloma, 5 incipient and 17 fully developed carcinomata, of which 6 were associated with metastases in the lymphatic glands and lungs. In addition to the local effect the painting with tar produced general toxic changes in the internal organs, the spleen both myelogenous changes and amyloid degeneration were observed. The myelogenous changes began to develop in the first three or four weeks, and were present to a marked degree after seventy four days' painting. Amyloid degeneration was not definitely found until 250 days. The liver showed a considerable epithelial degeneration with abundant intracellular deposit of pigment as well as multiple infiltrations of lymphocytes and polymorphonuclear cells. All the animals that lived more than 100 days showed chronic interstitial nephritis. The lungs in most of the animals were the seat of bronchitis and sometimes of bronchopneumonia. All the examined showed particles of tar deposited in the

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine

### 158. Etiology of Erythema Nodosum

M. ARBORELLIUS (*Acta Vet Scand*, May 31st/1927 p 337) draws a distinction to the current belief that erythema nodosum is rare in adult males and he quotes A. A. LINDAU (Bj Med Medikal Jotning, 1925 vol 1 p 651) as recording, 17 female and 18 male cases before puberty and 33 female and only 4 male cases after puberty. Arborellus has however observed as many as 40 cases in young male adults, in a military hospital in Stockholm in the five year period 1922-26. The temperature was raised and the rate of sedimentation of the erythrocytes was greatly accelerated in the cases including majority. With two exceptions (these two cases were exceptional in several other respects) a violently positive reaction was obtained to Mantoux's intracutaneous test with 0.05 m. of old tuberculin. The physical examination of the lungs yielded no very definite results, but in as many as 29 cases the x-rays showed definite changes in the hilus on one or both sides. In no case however, was there evidence of active pulmonary tuberculosis. The author concludes that though erythema nodosum may in most cases be the expression of a recently acquired tuberculous infection it may occasionally appear as the result of other morbid conditions.

L. A. LINDAU (*Acta Paediatr* May 23rd 1927 p 402) records observations at a children's hospital in Gothenburg between January 1st 1922 and September 1st 1926. In the case of every child admitted inquiries were made as to a history of erythema nodosum, a special place in the records being reserved for this information. In none of the 129 cases of erythema nodosum treated in hospital in the period under review was there, at the same time, pain in or swelling of the joints. Of a total of 130 cases of erythema nodosum in children between the ages of 1 and 14 only one was reported to have previously suffered from some rheumatic affection. Of the other hand among the cases of acute polyarthritis acute osteoarthritis and chorea minor (a total of 1.6) treated in hospital there were only 4 with a record of erythema nodosum at some earlier date. In all these 4 cases the Piquet reaction was positive and in 3 of them there were signs suggestive of tuberculous pulmonary disease. Most of the cases of erythema nodosum belonged to the age period 3-10 whereas the rheumatic affections did not become frequent till after the age of 6. The seasonal incidence was also different erythema nodosum occurring usually in the spring, while the three rheumatic affections under consideration were most frequent in the winter and spring. The author concludes that his material provides no proof of the assumption that erythema nodosum and the three rheumatic affections studied have any connexion with each other.

### 160. Pyrexia in Congenital Syphilis

G. VERRI (*Il Policlinico Sez Prat*, July 18th 1927, p 1077) publishes ten cases of fever due to congenital syphilis. He finds that this form of pyrexia may appear at any time or life in his series the ages ranged from 5 to 45 years. It may be remittent or continuous in type and persist from one month to three years in the majority of cases it is related to some concomitant lesion. The general health is more affected by the organic lesions present than by the temperature. Concomitant disease may mitigate the fever of congenital syphilis it may disappear under non-specific treatment but yields more surely to mercury or arsenobenzol.

### 161. Bronchial Spirochaetosis

J. GATE and M. BILLA (*Presse Med* April 23rd 1927 p 513) record their observations on 32 cases of this condition which was first described by Castellani in 1905. Eight cases were examples of active pulmonary tuberculosis the sputum was mucopurulent with haemorrhagic striae. It was always found that the discovery of the spirochaetes coincided with an aggravation both in the physical signs and general condition. In 17 cases, 12 of which were acute and 5 chronic the spirochaetes was an independent infection resembling influenza. It was in the acute forms that the expectoration was most characteristic, consisting of mucous and saliva of a brick-red colour. In the chronic forms the sputum was mucopurulent with haemorrhagic striae. In 7 cases in which the sputum was examined no clinical history was available. Treatment consisted in the use of novarsenobenzol three injections of which in doses of 0.15-0.30 and 0.45 gram, were sufficient, or in the administration of stovarsol

by the month in doses of 0.50 gram daily for ten days. The acute forms yielded most readily to treatment, but some improvement also occurred in the chronic forms. In the tuberculous cases the ordinary spirochaetocides were apt to give rise to fibrile attacks and were therefore best avoided, except in chronic cases.

### 162. Pernicious Anaemia in a Boy

D. O'HARA and J. S. GREW (*Boston Med and Surg Journ*, July 28th 1927 p 129) report an unusual case of pernicious anaemia in a boy aged 14 who after being discharged from hospital during a remission, remained well and able to work for two years. He relapsed subsequently and on re-admission had an ashy pallor but no jaundice, for the next five months the white blood cell counts were mostly below normal any fluctuations being due to changes in the number of polymorphonuclear cells. Soon after admission 700 c.c. of whole blood were transfused because of the rapidly decreasing blood values accompanied by epistaxis haematemesis, and melæna. This tide over the crisis and apparently stimulated blood formation for about a week later there appeared a sharp increase in the reticulated red cells (2+ per cent), and one nucleated red cell underwent mitosis was found. In the fourth month a series of small transfusions were given without much effect more with the idea of providing some theoretical hormones in small repeated doses than of supplying blood cells. During the first attack no liver was given, and only very small amounts during the second relapse, because of the difficulty in getting the patient to take it. Achylia gastrica was present and the bone marrow of the tibia was cellular showing the megaloblastic hyperplasia described by Peabody as characteristic of adult patients in a relapse. At the time of reporting a third relapse was anticipated in the near future and the amount of liver in the diet was known to be inadequate the patient could only be persuaded to take it mixed with ice cream.

### 163. Meningeal Haematoma due to Encephalitis

D. LEROUX (*Bull et Mem Soc Med des Hop de Paris* June 9th 1927 p 805) who records an illustrative case state that while formerly many cases of meningeal haemorrhage in young persons were attributed on mere presumptions to tuberculosis at the present time it is generally admitted that epidemic encephalitis is responsible for many cases of meningeal haemorrhage curable or otherwise. Darleguy's patient was a sailor aged 17 in whom the symptoms did not indicate meningeal haemorrhage but encephalitis. The first lumbar puncture showed an aseptic meningeal reaction and the second and third in excess of albumin without an increase of cells. The symptoms consisted of progressive tetraplegia with tonic spasm of the head and left upper limb. Death took place on the tenth day of the disease and the necropsy showed congestion and rupture of the vessels of the cerebral peduncles, lentiform nuclei and optic chiasm with an abundant infiltration of leucocytes which is a very important histological lesion in epidemic encephalitis.

### 164. Agranulocytosis

H. VOS and T. A. STAAL (*Nederl Tydscr Geneesk* May 28th, 1927 p 2933) state that in 1922 Schmitz and Verse gave this name to a series of cases they had observed characterized by severe gangrenous processes especially in the tonsils, and ending fatally in a short time. Examination of the blood of these cases showed that while the haemoglobin value and number of red cells were practically normal there was always a very distinct leucopenia due to the more or less complete disappearance of all the polymorphonuclear cells. On the other hand the number of lymphocytes and large mononuclears were normal and only slightly diminished. The original cases of Schmitz and Verse showed a close resemblance to one another. The disease occurred exclusively in middle aged women who developed gangrenous processes in the tonsils and elsewhere. Glandular enlargement was never generalized at most only localized there was slight jaundice, no anaemia and no haemorrhagic diathesis. The bleeding and coagulation times were quite normal. There were no characteristic urinal findings in the internal organs or in the urine. Death occurred in a few days or weeks of course the result of degenerative pneumonia. *Poet mort* in the most characteristic signs were found in the bone marrow which showed the same changes as in the peripheral blood. Schmitz and Verse's paper was followed by a number of other, almost exclusively by German and a few American writers so that about 40 cases of agranulocytosis have been recorded. It has

been shown that though the great majority occur in women, undoubted examples may also be found in men. Iotens is absent in a considerable number of cases. The gangrenous process is not always confined to the buccal cavity, but may attack any part of the alimentary canal from the oesophagus to the rectum, as well as the intortus vaginae, and the lesions may sometimes be absent in the tonsils and occur elsewhere. The course is not always fatal. The disease may be due to various causes, probably, in most cases, of an infective character. The blood picture and absence of haemorrhagic diathesis serve to distinguish it from septicæmia, aplastic anaemia, and leukaemia.

#### 155 Encephalitis in Measles

J. B. NEAL and D. APPELBAUM (*Journ Amer Med Assoc*, May 14th, 1927, p. 1552) state that while they have seen a few instances of encephalitis following other acute infectious diseases, the largest number—namely, twelve—have been associated with measles. The clinical picture was very variable. The onset was usually sudden during, or a few days after, the attack of measles. Fever and headache were almost constant, but vomiting occurred only occasionally. Convulsions were present in about half the cases, and were sometimes very severe. The most striking symptoms were referable to the mental condition, which was characterized in some by irritability or apathy and in others by profound stupor or delirium. Paralysis of various muscles or groups of muscles occurred in one third of the cases. In two patients there was paralysis of the right rectus externus, associated in one with right facial paralysis. Another patient had spastic paralysis of the left arm, which cleared up in less than a week, and the fourth patient had spastic paralysis of the left arm and paralysis of the left side of the face and left leg. Hyperaesthesia was fairly common. Signs of meningeal irritation, such as nuchal rigidity, Kernig's sign, Brudzinski's sign, a bulging fontanelle, or a positive Macewen sign, were noted in a fair proportion of cases. The reflexes might be exaggerated, normal, or absent. The spinal fluid was usually under increased pressure and showed a slight or moderate increase of mononuclear cells. The sugar content was uniformly normal or high, and smears and cultures were negative for microorganisms. Three patients died and six of the nine who were followed up made a complete recovery.

## Surgery.

#### 166 Orbito-ethmoidal Osteomata

H. CUSHING (*Surg, Gynecol and Obstet*, June, 1927, p. 721) reports four cases of orbito-ethmoidal osteomata with intracranial complications. All four patients were men, and three had scars of old frontal scalp wounds. In one case death was due to infection owing to failure to close off the communication between the meninges and the nasal cavity, and in another to delay in operating. Cushing concludes that these ethmoidal osteomata should be removed as soon as they are diagnosed by the x-rays, since delay may result not only in the occurrence of the familiar intracranial complications, but also of the little understood intracranial variety. In this series of four cases there occurred a cerebrospinal rhinorrhoea communicating with the ventricles, a large intra-cerebral pneumatocele, and an intradural mucocoele. Since the majority of these ethmoidal osteomata may ultimately lead to intracranial complications Cushing considers that they should be approached through an exploratory frontal osteoplastic craniotomy rather than through the nose or the orbit. He thinks it possible that mild frontal injuries may produce a fissured fracture of the thin floor of the anterior cranial fossa or a diastasis of the suture between the orbital plate of the frontal bone and the adjacent edge of the ethmoid bone roofing the ethmoid cells; it was at this point of union that the intracranial projection of the tumour was found in each of the four patients.

#### 167 Diagnosis of Renal Colic

O. A. SCHWARTZ (*Med Welt*, July 16th, 1927, p. 876) refers to the difficulties in diagnosis of renal colic, especially in right-sided pain, where affections of the appendix and gall bladder must be considered, in addition to gynaecological and intestinal disturbances, gastric ulcer, ileus, and the gastric crises of tabes. He advocates examination of the urine, both chemical and microscopic, with the proviso that a negative result does not rule out disease of the urinary tract, and adds that this examination and palpation of the kidneys should be followed by an x-ray examination of the whole urinary tract. This may show abnormality of the kidney shadow, or the presence of a stone and its size and position, the possibility of its passage may thus be estimated. Since certain calculi give rise to no shadow, a negative result in

this respect does not exclude the presence of a stone. Shadows may be caused also by conditions outside the urinary tract, such as calcified mesenteric glands and phleboliths, and further examination is necessary to deduce their position. The renal functions are tested by intravenous injection of indigo carmine, the excretion of the dye is watched through the cystoscope, and the bladder and ureteral orifices are examined at the same time. When x-ray shadows appear an opaque ureteral catheter is passed to determine whether they are due to conditions within the urinary tract or outside. If the catheter shows any suspicious signs in the renal pelvis its outline and that of the calyces should be demonstrated by an x-ray examination after the injection of an opaque fluid, this also defines the exact position of the kidney. The bladder and urethra can be photographed in like manner, with a view to revealing the presence of a diverticulum or stricture.

#### 168 Massive Collapse of the Lungs

H. BERGAMINI and L. A. SHEPARD (*Annals of Surgery*, July, 1927, p. 35) record two cases of sudden death during operation due to massive collapse of the lungs. Post-operative atelectasis or massive collapse is usually a benign unilateral condition which occurs shortly after an operation, the collapse may be bilateral, and then causes sudden death. The condition has been attributed to paralysis of the muscles overlying the lung, and in other cases to obstruction of the bronchi. The authors state that the histological appearances in the lungs in their cases suggested that in the cause of the atelectasis was a vasomotor disturbance of reflex origin, possibly akin to angioneurotic oedema.

#### 169 Malignancy of the Thyroid

N. W. GILLETTE (*Amer Journ Surg*, June, 1927, p. 556) points out that early diagnosis in malignancy of the thyroid is desirable, but is very difficult as the same symptoms are present in other types of goitre, such as adenomatous and colloid goitre. The gland is hard and nodular in malignancy, as it is also with adenomata, loss of weight occurs in malignancy and with toxic goitre. Cancer of the thyroid develops slowly and forms metastases much more slowly than in breast and stomach cases. Early removal of all goitres in which nodules appear seems the only chance of preventing the development of malignancy. Carcinoma apparently does not develop in true Graves's disease, but appears where an early colloid goitre is present or where a nodule can be felt. The ordinary types of malignancy are adenocarcinoma, medullary or sarcomatous carcinoma, and sarcoma. About one sarcoma occurs to ten carcinomas. Metastases are usually seen in the bones or lungs. Carcinoma is present in about 3 per cent of all cases of resection. There appears to be no such thing as benign metastases of the thyroid gland, investigations indicate that there is no doubt that a thyroid which produces metastases is definitely malignant. Patients have a good chance of recovery if the diagnosis of malignancy is only made after operation by the pathologist. The author adds that a nodular gland is surgical, and early removal will save many from death from carcinoma.

#### 170 Abscess of the Spinal Cord following Typhoid Pleurisy

C. I. URECHIA (*Bull et Mem Soc Méd des Hop de Paris*, July 11th, 1927, p. 1137) records the case of a man, aged 23, who after pleurisy occurring at the end of an attack of typhoid fever developed symptoms of myelitis in the region of the lower dorsal segment, corresponding to the level of the pleurisy. On operation a large subdural abscess was found between the eighth and twelfth dorsal vertebrae. The operation undoubtedly saved the patient's life, but did not affect his paraplegia, which was complete and accompanied by slight paresthesia. The author thinks that this is an unusual case of an abscess in the spinal cord arising by direct continuity from a pleurisy.

#### 171 Non-venereal Genital Infection

T. BAKER (*Journ Amer Med Assoc*, June 25th, 1927, p. 2250) describes a number of cases of acute proctitis and epididymitis of non-venereal origin. In the etiology of these a septic focus, often due to *Staphylococcus aureus*, played an important part, and in some cases which were associated with or followed influenza or so-called influenza. He finds that the symptoms of these septic genital conditions may closely resemble those of venereal infections, they may occur in patients who have had gonorrhoea some years previously, without necessarily being gonococcal origin, and may, on subsiding, be followed by chronic septic foci which in turn may give rise to conditions as arthritis, rickets, pericarditis and pyelitis. The treatment of these acute non-venereal genital conditions by Baker is removal of distant septic foci and drainage of the local condition in the event of suppuration. Prolonged unresolved septic epididymitis, which

to 1 in 1,000) Instrumentation is necessary to open up and drain the urethral glands, but this should not exceed the minimum to promote drainage. Prostatic massage, necessary in some cases, should not be forcible, but consist of gentle and sustained pressure on all the palpable surfaces. The author has found aspiration of the urethra with the Mills negative catheter to be beneficial. Sulphur salivarian preparations are useful when given frequently in small doses subcutaneously to suitable cases at appropriate intervals. Protein shock therapy is recommended as the ideal treatment for rheumatism and other gonorrhoeal systemic manifestations, T A B vaccine being often used. The initial dose should be not less than 100 million organisms given in distilled water or saline, and the second 200 to 400 million. Combined with baths as hot as can be tolerated, this treatment has been found to relieve suffering in a remarkable manner.

177

**Rational Bromide Therapy**

O WUTH (*Journ Amer Med Assoc*, June 25th, 1927, p 2013) believes that bromide intoxication occurs much more frequently than is generally recognized, it is sometimes characterized by a variety of neurological symptoms and is often difficult to diagnose by the usual clinical methods. The concentration of bromides in the serum of a patient depends mainly on the relative intake of this salt and chlorides, if bromides constitute 25 to 30 per cent of the total haloids toxic symptoms are likely to appear and 40 per cent may be fatal. Except in such conditions of disturbed chloride metabolism as pneumonia and nephritis the excretion of chlorides balances the intake, therefore if the average chloride excretion (and intake) is low the dose of bromide should also be kept low. Wuth considers that for rational adequate dosage, and in order to avoid bromide intoxication, the administration of bromides, whether as a sedative or for epilepsy, should be preceded by an estimation of chlorides in the urine, and should be controlled by a qualitative test for bromides in the urine and their estimation in the serum. For this purpose he has devised a colorimetric method, using gold chloride, he states that it is simpler than the methods used by other workers, and should therefore be useful in controlling bromide medication clinically.

**Neurology and Psychology.****178 Hemiplegia associated with Extensive Naevus and Mental Defect**

T BRUSHFIELD and W WILTT (*Brit Journ Child Dis*, April-June, 1927, p 98) state that during the period 1914 to 1925 there occurred among a total of 2,412 mentally defective children admitted to the Fountain Mental Hospital three cases in which an unusual but characteristic syndrome was present, consisting of mental defect, extensive naevus, and hemiplegia. The mental defect was in each case of marked degree, the children being low grade imbeciles, who were unable to talk or walk, and were quite helpless as regards their bodily needs. The condition in each case had been present since birth, and the children all showed various stigms of degeneration. Extensive involvement of the skin by naevus was a striking feature of these cases. The markings were much more pronounced over the face and neck, but no part of the body was entirely free, the total area of the naevus covering approximately one third of the skin surface. In two cases there was left hemiplegia and in one case right hemiplegia. The usual features of infantile hemiplegia were present, such as contractures, wasting, and underdevelopment. No similar cases appear to have been recorded in the literature except one by E A Cockayne, in which left hemiplegia was associated with extensive naevoid markings, but without mental defect.

**179 Psychological Causes of Relapse in Drug Addiction**

L KOLB (*Journ Nerv and Ment Dis*, July, 1927, p 22) ascribes the relapse of drug addicts who have apparently responded well to treatment to the original cause of the condition—namely, a pathological nervous constitution with a sense of inferiority and unsatisfied cravings, the distress of which is temporarily relieved by narcotics. He finds that most of these patients make sincere efforts to be cured in the early stages, but, later on, undergo treatment only as a matter of expediency, the hope of recovery having waned by then, and additional factors, such as habit, memory associations and increasing physical dependence on drugs have established themselves, intensifying the original craving. Kolb regards the physical element in addiction as of less importance during the first two or three years than subsequently, but he gives the warning that the withdrawal of a drug from a patient who has used it for many years may cause prolonged hysterical symptoms, or even a mild and

transient form of mania. He believes that the apparent increase of cases of relapse in recent years is due to the fact that legislative restrictions have prevented the more psychologically stable persons from becoming addicts. Before these control measures were enacted a larger proportion of relatively healthy people came under the influence of drugs, and benefited by treatment, thus improving relatively the statistics of recovery. The author draws attention to the great danger of allowing the unstable type of patient after treatment to return to the old environment where the tendency started, and he adds that any unsatisfied desire is particularly likely to be transformed into a craving for narcotics. Uncongenial companionship, financial insecurity, and physical defects are common factors in relapse, and such patients require continued observation and careful treatment of the exciting cause.

**180 Centro-lobar Cerebral Sclerosis and Diffuse Periaxial Encephalitis**

C FOIX and J MARIE (*Progr Med*, April 2nd, 1927, p 417) refer to the case of diffuse cerebral sclerosis reported by Schilder in 1912 and describe three cases of this condition and one of encephalitis, giving the pathological findings in each. The lesions in centro lobar sclerosis are symmetrical, they involve the occipital lobe as far as the Rolandic convolutions, and roughly follow the coru of the lateral ventricle. The general characters of the cases conformed with those described by Schilder. The onset was fairly rapid, with sensory and motor disturbances, diminution of vision, hemianopsia, paresthesia of the left arm, and convulsions. The conditions became aggravated, amautosis, quadriplegia, and a congestion at the optic fundus (simulating cerebral tumour) developed, and death supervened in about six months from an intercurrent malady. In diffuse periaxial encephalitis the onset is characterized by a neurological syndrome consisting of visual disturbances, motor troubles, and psychotic phenomena. These become exaggerated with all the symptoms of intracranial hypertension, and death occurs from the disease itself in twelve to eighteen months after the onset. In formal preparations of the brain, a marked characteristic of centro lobar sclerosis is a greyish, hard area in the place of the white matter of the hemispheres. The lesion is symmetrical and the cortex entire. Changes in the meninges are also noted. Both these cerebral conditions have an identity of topography, but in periaxial encephalitis the lesion is yellowish and there is little retraction of the white matter. The fundamental difference between these two lesions lies in the histology of the meninges and vessels, an adult neuroglia rich in fibrils and a sclerosed perivascularitis are evidence of a cicatricial process in cerebral sclerosis, while the young neuroglia rich in cells, the presence of giant cells, sometimes nucleated, and of granular bodies, and perivascularitis with leucocytic infiltration indicate an evolutive process in encephalitis. The authors maintain that these are but two stages and two clinical varieties of one and the same malady. The diagnosis is often difficult, and conditions which may have to be distinguished are cerebral tumour, nervous syphilis, and optic neuro myelitis.

**181 Functional Ocular Spasms in Epidemic Encephalitis**

H ROGER and J REBOUL LACHAUX (*Ann de Med*, June, 1927, p 19) report that among the cardinal symptoms of epidemic encephalitis are proxysmal hypertonicity of the muscles of the eye, and describe eight cases illustrating this condition. The authors state that the frequency of these spasms is not very great, and they ordinarily occur some five or six years after the acute attack. The appearance and importance of these symptoms bear no relation to the intensity of the acute phase, nor are patients who have manifested the ocular signs common to encephalitis more liable to these later attacks. The spasms may be either tonic or clonic. The former are classed as (1) simple, in which the eyes move in one and always the same direction, (2) variable or alternating, the movements being sometimes in one, sometimes in another direction, (3) locking, in which the movements are successively in two directions, and (4) a simultaneous proxysm of the whole musculature of the eye, causing a fixed and staring stare. These spasms may be accompanied by a conjunctival deviation of the head. Clonic spasms displace the eyelids a series of rhythmical convulsive movements. The attacks which follow usually some exertion fatigue, or emotion, may occur sharply without any prodromes, but sometimes they are ushered in with a feeling of malaise, in which case vertigo. During the crisis the head is generally hyperextended, vision is impaired, and there are laryngeal, cardiac, respiratory, and psychic disturbances. The attacks generally last from a few seconds to fifteen or twenty minutes, in rare cases for some hours, they are usually recurrent daily or weekly. In the inter-attack periods patients may suffer from labyrinthine, cardiac, and

## Pathology.

## 187. Thermophilic Bacteria in Milk

MARION O. ECKFORD (*Immun. Journ. of Hygiene*, May, 1927, p 201) has examined a large number of specimens of milk, cream, cheese, and butter for the presence of thermophilic bacteria. No fewer than 312 out of 450 samples of raw and pasteurized milk were found to contain organisms capable of growth at 55°C. These organisms she divides into two groups: (1) the obligatory thermophiles, capable of developing at temperatures between 42°C and 63° or 75°C, with an optimum about 50° to 60°C; (2) the thermo-tolerant organisms, capable of developing between 35°C and 70° or 75°C, with an optimum about 50° to 60°C. The true thermophiles were Gram negative aerobic spore bearing bacilli, producing an alkaline coagulation in milk, sometimes with digestion. Their fermentative powers were very weak, none of them produced gas, and only a few produced acid from carbohydrates, most of them were non proteolytic. The thermo-tolerant bacilli were aerobic spore bearing bacilli, some Gram positive and some Gram negative. They produced no gas from sugars, but most of them produced acid from dextrose. They formed a small amount of acid in milk, and generally coagulated it. Their proteolytic powers were weak. Both groups proved non pathogenic to guinea pigs on injection. Though the thermophiles are able to grow in broth and on agar at a high temperature they did not multiply under experimental conditions in milk kept at 62°C. The thermo-tolerant organisms, on the other hand, multiplied enormously. The thermophilic organisms produced spores that could withstand a temperature of 120°C for fifteen minutes, the heat resistance of the thermo-tolerant group was 115°C for the same time. The interest of these observations lies in their relation to milk analysis. Since the thermo-tolerant organisms are able to multiply at 60°C there may be an actual increase in the number of bacilli during pasteurization, so that a milk which had a low bacterial count before pasteurization may have a high one after it. On plates made from pasteurized milk the organisms develop in the form of pin point colonies. Thermophilic organisms were never found in canned milk, but thermo-tolerant organisms of the *subtilis mesentericus* group were apparently found.

## 188. Local Resistance of the Cornea to Immunization

ELLORD and VILLARD (*Bull. de l'Acad. de Med.*, May 29th, 1927, p 607) report a case of accidental inoculation of the eye with vaccine lymph. Conjunctivitis appeared a few hours later, and in three days was intense, being accompanied by corneal erosion andritis. In eight days there was an intense irido-cyclitis, the cornea was densely infiltrated, opaque, and rapidly ulcerating. At the end of four weeks the eye became glaucomatous and intensely painful. As no relief was afforded by iridectomy, and there was some fear of sympathetic ophthalmia in the other eye, the damaged eye was enucleated after about two months. The authors comment on the extreme rarity of the accident, the early appearance of symptoms, the severe results in iritis, irido-cyclitis, and glaucoma, the fact that it occurred in a patient who had frequently been vaccinated, the last time seven years previously, and the failure of treatment. L. CANUS (*ibid.*, p 610) has found that while the skin of the shoulder or lower limbs remains comparatively refractory to reinfection in a vaccinated person the eyelids continue more or less susceptible and the cornea retains its susceptibility almost completely. Persons engaged in the preparation of lymph easily infected their fingers, though the skin at the ordinary site of vaccination remained immune. Canus reports some experiments in producing local passive immunity by replacing the aqueous humor with serum from an immunized subject. He thinks that the experiments indicate the local application in cases of accidental inoculation of the cornea of the serum from an immunized person.

## 189. Purification of Insulin

F. DICKENS, E. C. DODDS, W. LAWSON, and N. F. MACLAGAN (*Biochem. Journ.*, 1927, vol. xxi, No. 3, p 560) describe a method for the purification of insulin. Three operations are involved. The crude insulin is fractionally precipitated with trichloroacetic acid, the greater part of the active material comes down when the concentration reaches 2 per cent, but there is a further precipitate when the acid is brought up to concentrations of 3 and 5 per cent. The precipitate is collected, dissolved in decinormal hydrochloric acid, and half the volume of saturated sodium chloride solution is added. A precipitate is again thrown down, consisting of the active material, a considerable proportion of the inactive material remains in solution. The precipitate is dissolved in water, the solution adjusted to pH 4.0, and twice the volume of N/3 potassium oxalate solution is run in. This brings down

hydrochloric acid, is converted to the picrate, this is finally reduced to the hydrochloride. The principle of the method, therefore, depends on precipitating the insulin with the protein and metaphosphate fractions, and then making use of the differential solubilities of insulin and its accompanying inactive products in salt solutions at the isoelectric point. By this means it is possible to concentrate the active fraction to such an extent that one unit is contained in 0.02 mg of the finished product.

## 190. Phenol as an Antigen for the Wassermann Test

According to C. NINNI and G. MOLINARI (*Pathologica*, June 15th, 1927, p 279) certain mordants, such as aniline, paratoluidine, and phenol, are capable of functioning in place of the usual lipoidal antigen in the Wassermann test. They report that the best of these substances is a 2 per cent solution of phenol in 96 per cent alcohol, before use the solution is diluted 1 in 9 with saline. Using this antigen in an examination of 600 serums, they obtained almost complete agreement with the results given by three control antigens of the lipoidal type.

## 191. Action of the Pituitary Secretion on Ovarian Function

B. ZONDEK and S. ASCHHEIM (*Arch. f. Gynak.*, April 20th, 1927) have found that implantation into young mice of small grafts of the anterior lobe of the pituitary gland, taken from the cow or other animals or from male or female human subjects, is followed within three to five days by well developed oestrus, with (1) thickening of the vagina and appearance in the vaginal secretion of the microscopic characters typical of rut, (2) notable enlargement of the uterus, and (3) enlargement of the ovaries with sometimes corpus luteum formation. The ovaries show microscopically ripening of the follicle, development of a theca interna, and sometimes passage of an ovum into a fallopian tube. The granulosa cells exhibit partial or complete lutealization. The changes which follow the graft are very similar to those occurring in young mice after injection of ovarian hormones, such as oestrum and folliculin, extracted from the follicle or corpus luteum, with the important difference, however, that the results of anterior lobe hypophyseal grafts are entirely negative in animals which have been castrated, while oestrus is regularly induced by injection of ovarian hormone into castrated mice. Zondek and Aschheim conclude that production of the oestrogenic hormone of the ovary is set in action by endocrine influences derived from the anterior part of the hypophysis, which brings the follicular apparatus into activity, the uterus and vagina are affected secondarily by the ovarian hormone. They have found that no other ductless gland has an action similar to that of the anterior lobe of the pituitary, and they suggest that the ability of inducing oestrus in the non-castrated infantile mouse be adopted as the criterion of activity in extracts of the anterior portion of that gland. The anterior pituitary preparations currently used in therapeutics have been found by them to be devoid of effect.

## 192. The Effect of Ultra-violet Radiation on Resistance to Infection

CLAIRE M. HILL and JAMES H. CLARK (*Immun. Journ. of Hygiene*, July, 1927, p 418) have performed controlled experiments on albino rats to determine whether irradiation with ultra violet rays has any influence in increasing the resistance of the animals to infection with pneumococcus Type 1. The rats were divided into groups similar in weight, age, sex, and family, and one or more groups were treated with ultra violet rays for two and a half weeks, each animal was then injected intraperitoneally with 0.2 c.c. of an eighteen hour culture of pneumococcus diluted 1 in 10,000. The irradiation was performed with a Hanovia quartz mercury arc lamp placed 9½ inches from the shaved backs of the animals. The dose was measured in terms of lithopone units, one unit being equivalent to the amount of energy necessary to darken white lithopone paint to a reflection factor of 50 per cent. The total dose given during the pre-injection period varied in different experiments from 47 to 171.5 units. The animals receiving the larger doses developed severe burns on the back, accompanied by ulceration. There was little or no effect on the red and white cell counts of the blood in the irradiated animals, but there was a consistent rise in the platelet count from an average of about 750,000 in the controls to from 900,000 to 1,200,000 in the irradiated rats. The results of injection with the pneumococcus showed very little difference between the irradiated and the control rats. The more than could be accounted for by chance variation. The authors conclude, therefore, that there is no definite evidence in favour of the beneficial effect of ultra violet irradiation in increasing resistance to infection, and that there is no indication for employing it as a general therapeutic measure in infectious diseases.

### Diabetes in Children

ACCORDING to A. A. LEVY (Jamaica, N. Y.), June 15th 1937 p. 83, though the diabetic children in this hospital are apt to be particularly severe, the prognosis has markedly improved since the introduction of insulin treatment. In his recording sixteen cases of juvenile diabetes he said that the life of such children had been very considerably prolonged by the insulin and Levy reports that all the diabetic children treated in St. Mark's Hospital, New York during the last three years are still alive. In contrast with diabetic children readily respond to preventive treatment hence the importance of periodic health examinations. Excessive weight is rarely seen in diabetic children but they are very susceptible to acidosis and have a poor tolerance for diets rich in fats and poor in carbohydrates. Acidosis is best avoided therefore accumulate rapidly and lead to coma. Moreover children are highly susceptible to intercurrent infections such as measles which intensify and aggravate the diabetic condition. The alimentary particularly the protein requirements of children are high consequently the insulin dosage is higher in proportion to the body weight than in adults. Owing to the small quantity of blood and tissue fluids in children the amount of free glucose available is small and there is a greater likelihood of insulinlike hypoglycaemia. Levy has found it advisable to allow a moderate glycosuria. In uncomplicated cases he recommends a diet controlling 2 grams of carbohydrate and 2 grams of protein for each kilo of weight with an allowance for caloric requirement. Insulin is administered in commencing doses of 3 to 5 units administered before breakfast a watch being kept for hypoglycaemic symptoms. The dose is gradually increased 2 to 3 units at a time, until acidosis is controlled and the glycosuria reduced to a faint trace. Doses of more than 10 units should be divided into two or three parts, the larger one being given before breakfast and the remainder in the early afternoon. Warren has reported that the pancreas in diabetic children may be smaller but the amount of islet tissue is no significantly reduced to account for the disturbed metabolic and there is little of the pathological change in the islands or acini found in adults. When an intercurrent infection occurs the dose should be such as the patient can bear and the potency of the drug may be less in such cases the dose of insulin should be increased to 10 to 20 units. The urine being tested every two or three hours for sugar and diabetic acid. Levy, main aims that diet and proper hygiene can often anchor a the course of diabetes and that much good can be effected by educating parents in maintaining a suitable regime.

194. T. A. CLAWSON JR. and G. A. HAPPOG JR. (*Four -  
Inner Ind. J.*, June 2nd 1947, p. 25) record the case of  
a diabetic negroess aged 11 in which twelve successive  
periods of acidosis or coma occurred followed by death.  
The patient was admitted to hospital during each of these  
periods and though the diabetic condition became gradually  
worse and carbohydrate tolerance progressively less, she  
responded readily to insulin treatment. The attacks of  
acidosis and the fatal termination were due to neglect and  
dietary lapses and the authors consider that under more  
favorable conditions a happier outcome would have resulted.  
They add that when intelligent supervision is not possible  
the patients should be placed in a suitable institution and  
they suggest that public health authorities must conveniently  
assume this responsibility.

195.      Fatal Bullous Gangrenous Varicella.

1. GORDON and J. D. POLLETO (*Arch of Ped* June 1927 p 337) record a case of fatal varicella in a boy aged 2 years and 11 months. On admission to hospital his temperature was 0°, the pulse 144 and the respirations 44 - called over both lumbar regions the left buttock and both thighs and legs were studded with hemorrhagic bullae ranging in size from the ordinary chicken pox vesicle to that of a shilling. Death occurred on the fourth day after admission by which time the bullae had become filled with the excretion of pus from the calves which were studded with a purulent fluid. The rectum was in colour and presented a white necrotic area which invaded and undermined the surrounding tissue. At the necropsy the necrotic areas showed a cone shaped patch of hemorrhage the apex of the cone pointing towards the decubital area which was ulcerated. The bones

of the lungs had reached the stage of red hepatization Commenting on the case Holleston remarks that though varicella is rightly regarded as one of the most trivial disorders a serious epidemicum that no physician had ever seen a child die of the disease apart from a complication entirely unconnected with the exanthem was no longer applicable In all cases of chicken pox however, are extremely rare and usually examples of the gangrenous or haemorrhagic variety In the course of more than twenty five years level hospital practice this was only the third fatal case of chicken pox Holleston had seen the first being one of confluent bullous varicella and the second of the gangrenous type Complicatively few cases of varicella bullous which as first described by Crocq of Novich in 1830 have been recorded, and with one exception none have been particularly severe

## 192 Clinical Duration of Aortic Aneurysm

G. H. COOT (Quart Jour Med April 1927 p 331) reports a statistical examination of 707 cases of aortic aneurysm with a view to determining the duration of life in this condition in British subjects. In 503 cases in men of aneurysm of the ascending, transverse and descending thoracic aorta, the average age of the patients was shown to be 42 years and the average duration of the condition until death just over nine years and nine months. In 72 similar cases in women the average age was 40 years and the duration twenty-two months. Cases of aneurysm of the abdominal aorta numbered 122 in men and 10 in women the average ages in years of the patients being 35.9 and 35.7 respectively, the average durations were 18.1 and 23.6 months. Certain points in prognosis are illustrated by graphs and it is shown that there is a marked fatality in the case of aneurysm of the ascending aorta between the ages of 40 and 45 and a distinct increase of duration with advancing age the expectation of life at 60 being nearly double that at 35. Aneurysms in other parts of the aorta occurring at various ages are considered similarly and a basis is thus obtained for calculating the probable length of life of these patients at different ages.

## 197      Hyperaesthetic Acro asphyxia.

197 Hyperaesthetic Acro asphyxia.  
N. V. BEDVIK (Arch Int Med 1927 p 539) records  
two illustrative cases in men aged 34 and 50 respectively of  
this disease which presents the following clinical features:  
It is a chronic and progressive hyperaesthetic affection occurring  
in younger persons localized in the lower limbs and frequently  
bilateral. The consequences are arterial obliteration,  
ischemia asphyria and spontaneous progressive gangrene  
without a definite line of demarcation. The etiology is  
obscure. The lesions found in the vessels are principally  
an atheroma endarteritis and endophlebitis. In addition  
to hyperplasia of the intima productive of emboli are found  
in the media and adventitia so that the condition can be  
described as a productive arteritis and phlebitis.

## Surgery

### Excision of Ulcer of the Duodenum

199. Excision of Ulcer of the Duodenum  
E S Judd and G W Nixel (Surg Gyn col and Os tot, July 1927 p 17) consider that excision of duodenal ulcers with partial duodenectomy has distinct advantages over gastro-enterostomy in suitable cases. Since recurrence of the bleeding often follows gastro-enterostomy they have so far operated only in those cases in which hemorrhage was a predominant symptom and especially when the patient was young and had a short history. They contend that their procedure offers all the gastro-enterostomy does with the addition of removal of the ulcer. Fresh ulcers may form after excision but they do not appear so frequently as the case after gastro-enterostomy and such a recurrence in the duodenum is no so serious a matter as a jejunal ulcer. Although its application is being gradually extended the procedure has not yet been tried when the duodenum is firmly fixed in cases where long standing inflammation has converted the upper portion of the duodenum into a hard cord and in which there is considerable dilatation of the stomach with marked thickening of its wall. The operation consists in the excision of the anterior half of the pyloric sphincter together with the cap of the duodenum and the ulcer. In most cases the ulcer occurs in the cap of the duodenum and when this portion has been removed and the anterior part of the sphincter excised the opening of the

lower end of the stomach and at the upper end of the duodenum stand out just as the two openings of a gastrotomy after the posterior row of sutures has been inserted. The steps of the operation are not difficult so long as the tissues are well exposed. This is readily obtained if the operation is not attempted for ulcers some distance from the pylorus, or where firm fixation of the duodenum does not permit of its being readily mobilized. The immediate results were very gratifying. Convalescence was uneventful and free from vomiting, retention, and gastric distress, with ordinary precautions against soiling the wounds healed well.

#### 199 Surgical Treatment of Pyorrhoea

J W E GRAHAM (*Journ. Med Assoc S Africa*, June 25th, 1927, p 306) discusses the surgical treatment of pyorrhoea with the object of saving the teeth, the gums being operated upon in sections with ten days' interval between each sitting. Having painted with iodine and under infiltration anaesthesia a transverse incision is made, lingually and labially, around the cervical margins of the teeth down to the bone. From the extremities of the horizontal incision two vertical incisions labially and two lingually are made downwards for about half an inch and the two flaps are reflected with a periosteal elevator. The necks of the teeth are cleaned and polished, and all diseased bone is cut away with flushing burrs, pockets are curetted in the same way. After flushing with saline solution or a mild antiseptic the flaps are trimmed and stitched back in position with fine No 3 silk interdental stitches, which are removed on the fourth day. In selected cases with not too much bone absorption the operation is said to produce very good results, and though there is a certain amount of gum recession in healing the pockets and pus disappear. Treatment with the electric cauterizer, the loop being passed deeply into the pockets and around the tooth, is another effective method, for which it is claimed that all micro organisms are killed and that the healing cicatrization tissue effectively tightens the gum around the tooth.

#### 200

#### Treatment of Colles's Fracture.

V BSKELUND (*Acta Chir Scand*, July 28th, 1927, p 41) reports from the surgical polyclinic of the communal hospital in Copenhagen on the results obtained in the treatment of Colles's fracture during the past five years. As a rule the fracture was reduced immediately and without an anaesthetic, only when there was great deformity, a firm impaction, or the patient was very nervous, was a light ethyl chloride anaesthesia induced. Reduction was effected on the usual principles, and skiagrams were taken in two planes. The plaster splint was removed after six to eight days, when massage was started, it was continued till normal mobility of the limb had been approximately restored. The patients were instructed to move their fingers freely from the first day, frequent movements at the elbow and shoulder were also encouraged. Of the total of 342 patients, 119 were men and 223 women. In 206 cases an after examination was made. The results in these 206 cases were as follows: functional, 60 per cent excellent, 33 per cent good, 6 per cent "mean", and 1 per cent bad; anatomical, 55 per cent excellent, 36 per cent good, 9 per cent "mean" and 0 per cent bad. The author excludes from this material cases in which there was also fracture of the carpal bones or detachment of the epiphysis. The patients in the "mean" class were able to work, but were constantly in pain, and the movements were somewhat restricted. The author adds that these results are better than those published in the literature available, and that the period of treatment was somewhat long, being on the average six to eight weeks.

#### 201

#### Treatment of Endarteritis Obliterans.

E STULZ and P STRICKER (*Rev de Chir*, No 3, 1927, p 196) describe the results of treatment in eight cases of endarteritis obliterans by removal of the suprarenal body. This operation is based on the assumption that the arterial condition is due to hyperfunction of these glands. The patients were in an advanced stage of the disease, and many of them showed actual gangrene of the limbs. Histological examination of the obliterated vessels was more in favour of an organized thrombosis than an endarteritis. Examination of the suprarenal glands has, so far, disclosed little that was abnormal. The blood, after the operation, showed various modifications, including a diminution of the coagulability and alteration in the viscosity. Other operations have frequently failed to relieve the condition. The authors consider that the removal of the left suprarenal capsule by the extraperitoneal route is an operation devoid of risk, the mortality has been nil. The operation results in definite improvement, though its mechanism is at present not understood. The sequelae of this form of treatment are said to be sufficiently encouraging to warrant further trial.

## Therapeutics.

#### 202 Treatment of Whooping-cough by Serum

A STROL and I ANGULESCU (*C R Soc de Biologie*, June 3rd, 1927, p 1446) consider that whooping cough is a very serious disease in infants less than 3 months old, the mortality reaching 98 per cent. The severe paroxysms of coughing are accompanied by cyanosis and vomiting. Two cases in infants, aged 4 and 6 weeks respectively, are reported, in which cures were effected by the use of serum obtained from convalescents from pertussis. In the first case, on the twelfth day of the disease, 6 ccm of serum taken from a convalescent child was injected intramuscularly, and three days later an injection of 10 ccm of whole blood was given. In the second case, on the tenth and twelfth days of the illness, 5 ccm of serum from a child convalescent for a year was subcutaneously injected. The authors believe that this therapy modifies the duration of the disease, and particularly the paroxysmal period, which is shortened, and paroxysms and recurrences are rendered less frequent and severe and the expectoration is diminished. The paroxysmal being the grave period in whooping cough, these injections of convalescent serum have a salutary effect on the prognosis and evolution of the disease.

#### 203

#### Dangers of Intravenous Injection

J H CLARK (*Journ Amer Med Assoc*, July 2nd, 1927, p 21) believes that the intravenous injection of even simple substances, such as sodium chloride and dextrose solutions, may prove disastrous if the cardiac condition is neglected. He records four cases in which death supervened after the injection of a 10 per cent dextrose solution, followed in one case by the injection of physiological salt solution. The cause of these deaths was uncertain. The suggestion of impurities in the dextrose is discarded by the author, who thinks, however, that the possibility of idiosyncrasy to dextrose must be borne in mind. Hanzlik and Karsner, as the result of experiments in anaphylaxis, conclude that hypotonic solutions of sucrose were definitely injurious to the lungs, though the experiments did not include dextrose, the results implicate this sugar also. Hewlett has found that a dilatation of the ventricle may be caused either by a weakening of the muscle with a lessening of the ventricular tone or by intensifying the demand on the heart. Temporary increase of work leads to a further but transient enlargement of the heart. Excessive dilatation lessens the muscular contractile force, and the characterizing acute cardiac failure then supervenes, the dilated ventricle fails to expel the blood coming to it, while the venous pressure rises and favours distension of the ventricular cavity during diastole. If the demands are not reduced below the functional capacity of the weakened muscle the continued collection of blood in the dilated ventricle leads to death. Clark believes that this is what happens when intravenous infusions are administered to patients already showing cardiac impairment, as indicated by a weak, rapid pulse, he concludes that intravenous therapy is not innocuous, and that it is necessary to be careful in the choice of fluids for this treatment, especially if large amounts of fluid are to be given. If the injection is given slowly and close watch is kept on the pulse and heat by frequent blood pressure determinations during the injection, such fatalities should, he thinks, be preventable.

#### 204 Serum Treatment of Gonorrhoeal Rheumatism.

P RAVAUT and DUCOURTIOUX (*Ann de Derm*, May, 1927, p 266) discuss the treatment of gonorrhoeal rheumatism by injections of antigonococcal serum, and report some cases in detail. They believe that in order to get the best results the injections must be given intravenously as a rule, though in the case of the large joints the serum may be injected into the joint. Non specific serums such as the antidiptherial did not give as good results. In the septicemic forms of gonorrhoea the antigenococcal serum proved very beneficial, and in the articular types pain was quickly relieved and the risk of subsequent ankylosis was much lessened. They add that if proper precautions are taken no accidents are likely to occur.

#### Treatment of Vincent's Angina

205 ACCORDING to G BERNAL (*La med Ibera*, May 28th, 1927, p 590) the following five methods have been recommended for the treatment of Vincent's angina: (1) Local application of a concentrated solution of methyl blue, or gentian with a more dilute solution of this substance combined with potassium chlorate. (2) Local application of a concentrated solution of chromic acid to loosen the membrane and bring the acid in contact with the ulcerated surface, removing the excess of acid with a solution of hydrogen peroxide so as to

prevent its caustic effect. (3) Local application of oleic unsaturated preparations, such as castor-oil in distilled water or neutral glycerin combined with intravenous injection of these preparations. (4) Local application of a 10 to 20 per cent potassium tartro-bismuthate solution in oil or glycerin, combined with intramuscular or injection of a bismuth preparation such as metropol succinat or bismuth eto dylate. (5) Local application of preparations of arsenic and bismuth combined with intravenous injections of arsenical preparations. Bernal has obtained the best results by local application twice daily of a 15 per cent solution in oil or glycerin of potassium tartro-bismuthate combined with intravenous injections of neosalvarsan (0.30 gram) every three days and the local application of the same solution. This treatment, which is said to be specific, heals the lesions in less than a week.

## Laryngology and Otology.

### 206. Tuberculosis of the Larynx in Java.

H. MÜLLER and W. F. J. VAN WAREN (Nederl. Tijdschr. v. Geneesk.) May 14th, 1927, p. 2676, review the literature and record their observations on 101 necropsies on Javanese natives who had died of tuberculosis; their conclusions being as follows: Tuberculosis of the larynx is almost as frequent in Java as in Europe. Of the 35 cases which occurred among the 101 tuberculous patients, 27 were in men and 8 in women. In contrast with the incidence in Europe the ulcerative form is the rule and the hypertrophic form the exception. Lupus of the larynx is rare; the site of predilection is the epiglottis, which was affected in about 89 per cent, and involvement of the cartilages is rare. Primary tuberculosis of the larynx is, however, very rare, as in Europe.

### 207. Surgery of the Oesophagus.

ACCORDING TO F. PAPIN (*Reu. de Laryngol.* May 15th, 1927, p. 297) most of the surgery of the oesophagus is directed to neighbouring organs and is only indirect. In certain cases, however, surgery is applied directly to the gullet either in the neck or in the throat. He discusses the various types of gastrostomy and considers the inverted cone type of Fontano or Koder Sen to be better than the superficial cone or valve of Franck or Villar and than the intramuscular type of Hartmann. He remarks that gastrostomy is used not only to enable the patient to receive nutrition but also to allow retrograde dilatation of the stricture in non-malignant cases. In direct surgery in the neck the only condition calling for exposure of the gullet is a pressure diverticulum. It is reached anteriorly to the sternomastoid by passing between the vessels and the thyroid gland. The diverticulum can be removed or invaginated into the oesophagus. To reach the thoracic oesophagus the entrance may be to the right or left of the spinal column. In the former the azygos veins give much trouble, while in the latter the aorta is met with but can be retracted. The easiest route appears to be from the left below the bifurcation of the trachea. The author considers the transpleural route inferior to the mediastinal as the risk of infection of the pleura is considerable and the resulting pneumothorax is undesirable. In cases of obstruction of the oesophagus about the level of the diaphragm anastomosis between the fundus of the stomach and the oesophagus above the stricture has been made. The fundus is brought up through an aperture in the diaphragm and the operation is performed transpleurally. In cases of mega-oesophagus or cardiospasm Greig has devised an operation for cutting the fibres of the diaphragm in the proximity of the oesophagus and at the same time cutting the phrenic nerve. Progressive dilatation is often required in addition to this manoeuvre.

### 208. Chronic Rhino-pharyngeal Disease.

B. R. SHURLEY (*Arch. of Oto-Laryngol.* March 1927, p. 220) considers that a considerable proportion of what patients refer to as tonsillitis, sinusitis and nasal catarrh is really rhino-pharyngitis which is mostly caused by varying degrees of obstruction. The author has found that the experimental occlusion in animals of one or both nostrils has a marked effect on vitality and resistance and in many cases death results. Local disease of the respiratory tract occurs, asthma and emphysema being particularly noticeable, whilst the and emphysema being particularly noticeable whilst the heart is dilated. There are changes in the oxygen-carbon dioxide metabolism in the blood, the silic becomes atrophic and if hair or feathers are present they are shed. Sharply and regards a free air passage of the utmost importance and regards that septal deflection, polypoid adenoids and sinuses disease should be rigorously treated. He thinks that the

turbinals should be respected on account of their function of warming and moistening, the inspired air. Septal deflections are very common in the highly evolved Caucasian type of skull, and disease of the turbinals and sinuses is only to be expected when they are subjected to the dry heat of a modern centrally heated house and to the winter cold out of doors of zero or below.

## Obstetrics and Gynaecology.

209

### Painless Childbirth.

A. HARRAN (*Amer. Journ. Obstet. and Gynecol.*, April, 1927, p. 485) states that during the last three years the Gwathmey method of rectal ether analgesia in labour has been used in 5,800 cases with very satisfactory results. A quarter of a grain of morphine is given hypodermically with 2 c.cm. of 50 per cent solution of magnesium sulphate to prolong the action of the morphine. In half the quantity of ether required for rectal anaesthesia is dissolved about 20 grains of quinine alkaloid, and a 4 oz. mixture is instilled into the rectum as a retention enema. After an interval of one to four hours following the injection of morphine and magnesium sulphate when the patient again complains of pain which is usually in from two to three hours a second or even a third rectal instillation of ether may be given at intervals of three hours or more. In 85 per cent of the cases pain was greatly relieved, there was no prolongation of the perineal stage or increase of forceps delivery. The only contraindication to the procedure is uterine inertia and the only restriction is not to start too soon. The patient should be in active labour with pains every four to five minutes, and in a 2 para the cervix should be allowed a dilatation of two or more finger tips. Harran claims that the applicability of this method is much greater than that of scopolamine anaesthesia. It can be used safely and effectively by the practitioner in confinements at home and does not require the service of a trained anaesthetist.

210 M. S. NAIDITSCH (*Zentralbl. f. Gynäkol.*, April 30th, 1927, p. 1123) records his experience of Gwathmey's method of anaesthesia in childbirth. From comparison with groups of cases in which either the morphine and magnesium sulphate injections or those of ether were omitted Naiditsch concludes that there is no special synergism of the ether with the other medicaments; the action of the former is not prolonged by the injection of the latter. Nevertheless by the use of the morphine and magnesium sulphate injections it is possible to defer the use of ether until a later stage of labour and so to secure more satisfactory anaesthesia during the end of the second stage. In primiparae the subcutaneous injection may well be repeated several times. Full analgesia was attained in more than half of the cases and pain was diminished in all although they groaned during uterine contractions the patients declared when questioned that they were free from pain. The anaesthetic effect of the ether lasted five or six hours and Naiditsch prefers to give it in two to three doses at one to two hourly intervals. He considers the method most useful in labours which are not likely to be prolonged and in which the uterine contractions are good.

### 211. Torsion of the Fallopian Tube.

G. BERTONE (*Ann. d. Ostet. e Ginecol.* April 30th 1927, p. 226) refers to three varieties of tubal torsion described in the literature—torsion round a pedicle performed by reason of tubal tumour or tubal pregnancy (15 cases), torsion of normal adnexa (15 cases) and torsion affecting a normal tube only (18 cases). There have been four instances of torsion of the normal tube during pregnancy, in a case described in the present communication the torsion occurred or recurred at the beginning of labour. During the sixth and also during the seventh month of otherwise normal pregnancy a primipara aged 27 had suffered from violent but spontaneously regressing attacks of pain in the left iliac region, slight but recurrent, which had been felt intermittently during the three weeks preceding labour and a violent recurrence led the midwife to summon medical aid about six hours after the commencement of labour when the thinned out cervix allowed introduction of two fingers. Muscular rigidity was well marked over the left iliac fossa. Morphine was given on several occasions, but after forty-eight hours it was found that labour had advanced not at all, pain was still present and the temperature had risen. At laparotomy it was found necessary to exteriorize the uterus before exposing the Fallopian tube, which was axially twisted three and a half times together with the adjacent part of the broad ligament, infiltrated with blood. The left ovary was normal. The

left tube having been excised, a living child was extracted by Caesarian section. Bertone states that torsion of the tube usually takes a clockwise direction, and that it is more common on the right side, being usually taken for acute appendicitis. The ultimate etiological agent is probably increased pressure in the tubal veins, which Payr has experimentally shown to induce axial rotation.

## 212 Extravascular Opening of the Ureter

N. KUDJI (*Zentralbl. f. Gynäk.*, May 7th, 1927, p. 1182) states that fifty cases have been recorded of extravascular opening of the ureter—into the urethra, vagina, or vestibulum. Opening of the ureter into the uterus has not hitherto been reported, except in non-viable foetuses in association with other severe deformities. Kudji records the case of a single woman, aged 21, who complained of urinary incontinence both by day and by night, although micturition was performed at intervals in the ordinary way, the labia majora and the inner sides of the thighs were moist and eczematous. Bimanual examination and an investigation of a catheter specimen of the urine gave normal findings, and no sign of a vaginal fistula was detected, although careful observation showed that the external os uteri was the site of a slight watery discharge. Cystoscopic appearances at first seemed normal, including those of the region of the ureteral openings on both sides, entrance of urine, however, could not be demonstrated on the right, nor could a ureteral catheter be passed on that side. After the intramuscular injection of indigo carmine, blue coloration was visible on the left within three minutes, but not on the right after half an hour; twenty minutes after the injection the urine exuding from the os uteri had not become colored. Catheters introduced into the urethra and in the cervix for seven hours gave issue to 350 and 32 c.c. respectively of urine. The diagnosis was accordingly made of a normal kidney and ureter on the left, and on the right of pronounced hypofunction of the kidney, with opening of the ureter into the uterus. The findings at laparotomy were confirmatory. Near the bladder the right ureter divided into two stems, of which the thicker passed forward and perforated the right wall of the cervix uteri close to the uterine vessels, and a thinner stem ended blindly during its passage towards the vesical trigone. Treatment consisted in division and suture of the ureter 1 cm. above its division and removal of both the branches below the point of section, no trouble in connection with the left kidney followed.

## Pathology.

### 213 Serological Test for Kala-azar

L. E. NAPIER (*Indian Med. Gaz.*, July, 1927, p. 362) describes a test founded on the accidental observation by Major Chopra that when the serum of a kala-azar patient is mixed with certain pentavalent compounds of antimony a heavy precipitate was formed. Trial was made of six such compounds, and the intensity of the reaction appeared to vary directly with the therapeutic efficiency of the drug used, stiburea (urea stibumina) proved the best. The test was performed in a series of sixty clinical cases, the results being compared with those of the aldehyde test and of spleen puncture or other positive test for the presence of Leishman, a small number of control tests on cases other than kala-azar were also made. Napier believes that the reaction is very reliable and equal in diagnostic value to the aldehyde test at least. It requires only a very small quantity of serum and gives a clear cut result, even when the serum is milky. The test is performed by adding two drops of twenty-four hour-old serum to 2 c.c. of a 0.25 per cent solution of stiburea, or two drops of fresh serum to 2 c.c. of a 1 per cent solution of stiburea, agitating and setting aside for ten minutes. If the donor of the serum is suffering from kala-azar a heavy flocculent precipitate will form, and in ten minutes will separate, leaving a clear supernatant fluid.

### 214 The Occurrence of Abnormal Pneumococci in Vivo

H. A. REIMANN (*Journ. Exper. Med.*, May 1st, 1927, p. 807) has tried to ascertain whether pneumococci undergo variation in the animal body. In the test tube under unfavourable cultural environments the smooth or S form of pneumococcus produces variants, which differ from the original type in no longer forming the specific carbohydrate element responsible for type specificity, in being agglutinated by heterologous serums, in being non-virulent for mice, and in being highly susceptible to phagocytosis. These variants are generally spoken of as the R or rough form of pneumococcus. An

intermediate form also occurs, which is less virulent than the original S form, and which shows certain serological differences. By animal passage it is possible to restore the original virulence and type specificity of this form. On the other hand, by placing it under unfavourable cultural conditions this transitional form is converted into the non-virulent R form. So far the only discovery of the R form of pneumococcus in the animal body has been in horses that were undergoing immunization with this organism. Under experimental conditions in the laboratory the author has succeeded in bringing about this change in guinea pigs and rabbits. Liquid agar containing Type 1 pneumococci was injected subcutaneously into guinea pigs that had been actively immunized against Type 1 cocci. Repeated cultures made from the agar focus showed the presence of S forms alone until the fifth day after injection, when a few R colonies appeared. These R forms persisted for about six weeks, they were, however, greatly outnumbered by the S form. In another experiment small phials containing an agar culture of pneumococcus Type 1 were inserted subcutaneously in rabbits. The neck of the phial was closed by a collodion membrane to allow the diffusion of serum but to prevent the passage of leucocytes. Agar was aspirated from the phials at intervals. It was found that the R forms appeared from the third day onwards, and remained demonstrable for periods up to eight weeks. Though they were often present in considerable numbers they never entirely replaced the S forms. Similar phials kept in tubes of normal rabbit serum at 39°C. never showed R forms. The author has therefore shown that R forms may appear *in vivo* in laboratory animals, but has not yet been able to determine what part this transformation plays in the natural recovery of patients from pneumonia.

### 215 Estimation of Antitoxin in Scarletina Serum

R. DEBRÉ, M. LAMY, and H. BOYNET (*C. R. Soc. de Biologie*, July 1st, 1927, p. 214) observed that in Dick negative cases a reaction could be obtained by increasing the dose of toxin. Some persons react to very much smaller quantities than others, who may be very resistant, and require the injection of 20, 50, 100, or even 200 skin doses before reacting positively. The authors, therefore, tried to find out whether there was a quantitative relation between the resistance of the skin and the amount of circulating antibody. They withdrew serum from a number of patients showing different degrees of skin susceptibility, diluted it progressively, mixed these dilutions with streptococcal toxin, and injected them into Dick positive persons. In this way they ascertained the amount of serum necessary to neutralize a given amount of toxin. The neutralizing dose, or that amount of antiserum necessary to neutralize one Dick dose of toxin, as tested on a susceptible subject, they call one antitoxic unit. The serum, for example, which neutralized one Dick dose of toxin in a quantity of 1/100 c.c. would be said to contain 100 antitoxic units. They were thus able to establish the existence of a parallelism between the skin reaction and the amount of antibody in the serum. They calculate that a person who can just resist one Dick dose of toxin intracutaneously contains in his serum about 20 units of antitoxin per cubic centimetre, and add that though this relation is not surprising theoretically, it is likely to be of great value in practice. It affords an indirect method of gauging the activity of the serum of a number of persons in order to find out which is the most suitable for therapeutic injection or for use in the Schultz-Charlton reaction. All that is necessary is to inject a series of Dick negative persons with increasing doses of toxin, and observe which of them are most resistant; it may be concluded that these have the greatest amount of antitoxin in their serum.

### 216 The Blood in Hodgkin's Disease

G. AUBERTIN (*Paris Méd.*, July 2nd, 1927, p. 30), as the result of the study of 100 cases the diagnosis of which was confirmed by *post mortem* examination, concludes that the essential haematological feature of Hodgkin's disease is a neutrophil leucocytosis which is constant, chronic, and persistent, but liable to fluctuations, it is distinguished from the polymorphonucleosis of chronic infections by being constantly associated with a moderate eosinophilia. This change in the blood picture is readily explained anatomically as it appears to be derived directly from the affected glands in which neutrophil polymorphonucleosis and eosinophils predominate. The etiological explanation is more difficult, but the leucocytosis associated with an oscillating fever suggests a glandular reaction of an infective nature, which is probably microbic or possibly parasitic owing to the eosinophilia. In any case the contrast with the lymphomatous hyperplasia of the lymphatic reaction

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine

## 217      Nervous Complications of Variola

R. E. Wilson and F. L. Loun (1914, *Johns Hopkins Hosp. Bull.*, June 19, p. 33) state that the older medical writers described a great variety of nervous complications of variola including delirium, psychosis, local and multiple neuritis and even hemiplegia and aphasia. The conditions are no peculiar to variola but are due to bacterial intoxication and invasion of the blood by secondary organisms. There is reason to believe however that certain neurological syndromes referable to the spinal cord and brain are due to invasion of the nervous system by the virus of variola. The present authors classify the recorded cases in the following groups: (1) Cases of paralysis of the legs without other symptoms. The clinical picture indicates an involvement of the anterior horn cells in the spinal cord; death occurred in all but one case from bed ore urinary infection or respiratory paralysis. (2) Several writers have noted hilar symptoms with dysarthria and disturbances of swallowing, none of these patients died and most recovered completely. (3) This group showed signs of a more diffuse process in the nervous system including spastic weakness, tremor at rest, bulbar disturbances and in some cases mental changes. The early and fairly uniform appearance of nervous symptoms in this group suggests that they are due to the virus of variola and not to secondary infection. Seven autopsies which were performed on cases with spinal symptoms showed either no changes at all, or areas of inflammation and degeneration.

### 2.8. Diagnosis of Arterio sclerosis of the Pulmonary Artery

E. SIGNORELLI (*Pit. Act.* July 4th 1927 1 631) describes in detail the clinical history and post mortem findings of a case of arterio-sclerosis of the pulmonary artery. He concludes that this condition can be diagnosed during life by (1) the intense persistent and diffuse cyanosis which is quite disproportionate to the degree of dyspnoea (2) the well marked hypertrophy and dilatation of the right ventricle and auricle, with insufficiency of the tricuspid valve (3) the occurrence of paroxysmal attacks of *Interdum accessione dolorosa adspueret retrosternal aenlur* during which the cyanosis reaches its maximum intensity (4) systolic diastolic murmurs over the pulmonary area caused by the relative stenosis and insufficiency. The necropsy showed a sclerosis of the pulmonary artery with obliteration and narrowing of the terminal branches and dilatation of the medium and large branches with thrombotic plagues. It was not possible to assign a syphilitic origin to this case. Signorelli reports a case in which the sclerosis of the pulmonary artery presented a pathological symptomatology associated with a syphilitic aetiology. It was definitely syphilitic.

## 219 Spirochaetal Jaundice in North America

H H LOWE and J E WALKER (*Journ Amer Med As* of July 9th 1927 p 86) review the literature and record the first case of spirochaetal jaundice reported in North America. As is the rule in this infection the case was sporadic. They think that spirochaetal jaundice is probably prevalent in the United States though it includes only a small proportion of the cases classified as infectious jaundice of unknown etiology before the discovery of *Leptospira icterohaemorrhagiae*. The disease is usually associated, according to the literature with polluted water or soil possibly being caused by the spirochaetes living free in nature. It is also possible that the part played by rats in the dissemination of the disease has been over emphasized. The authors' patient was a man aged 31, the symptoms were typical and he recovered. Although direct examination of the blood was negative the leptospira was recovered by guinea pig inoculation.

## 220 Aberrant Lymphomata in Chronic Lymphadenoma.

P. FOLTZ (*Il Policlinico Sez. Med.* August 1927 p. 389) records three cases to illustrate the occasional complication of the diagnosis in chronic lymphadenoma by the proliferation of lymphoid tissue in organs which are not usually involved in the hyperplastic process. A man aged 52 suffered from multiple lymphomata in the voluntary muscles but he was anaemic and had no characteristic blood reaction diagnosis during life was almost impossible. Much lymphoid tissue was found at the necropsy and in particular, there was a large mass in the bony pelvis. The

size of a foetal head. The upper limbs presented multiple nodules of a pasty consistence, ranging in size from that of a small nut to a mandarin orange. They were situated in the muscular substance of the biceps and triceps and in the superficial flexors of the forearm. The skin over them was movable, and neither thickened nor infiltrated. On incision the nodules were clearly gelatinous and sometimes reddish or haemorrhagic; their periphery retained some muscular structure. The size of the nodules diminished temporarily during x-ray treatment. Microscopically it was found that leucocytic tissue had invaded the muscular fibres, a condition of great rarity. Another man aged 59 had been a heavy drinker; he was wasted and suffered from loss of appetite, dyspnoea and glycosuria. He had a sense of weight in the abdomen and some epigastric pain but continued to work until he noticed an abdominal swelling. He was admitted to hospital with some fluid in the abdomen and enlargement of the cervical axillary and inguinal glands; a blood examination was negative and percutaneous abdominocentesis revealed a simple transudation. He died of heart failure due to fatty degeneration of the muscular parietes. At the pyloric end of the stomach there was a large oval ulcer extending into the greater curvature; it was two inches long and one and a half inch wide. On incision the bottom and edges were found to be infiltrated with lymphoid tissue; the rest of the stomach being healthy. The presence of ascites might have led to a diagnosis of cirrhosis of the liver. Holtz remarks that lymphomatous must therefore be numbered among the causes of ascites the constrictive action of lymphoid infiltration diminishing the lumen of the veins. Another patient had large polypous vegetations in the cardiac region of the stomach and also in the oesophago-gastric opening, projecting as much as one and a half inch. The author adds that the participation of the stomach in the hyperplastic process of lymphadenoma is somewhat rare and may make diagnosis extremely difficult.

## Surgery

## 224 Congenital Cysts of the Neck in Children

According to R L FAYE (*Inner Town Surg* July 1927,  
p 1) cysts are always surgical conditions and their cure  
depend on the embryonic structures from which they  
arise. The types usually seen are the thyroid gland, the  
hygroma - a lymphocystic branching cyst. The hygroma,  
often termed a lymphocoele is always of lymphatic origin  
and arises from the jugular sinus. It is usually found in the  
posterior triangle and is more common on the right side. It  
appears as a spongy tumour and may suddenly take on rapid  
growth often after trauma or infection. It may become tense  
when the child cries. The treatment is complete removal  
since otherwise recurrence always follows. Thyroglossal  
cysts are connected with the tongue and the thyrolo isthmus.  
Treatment depends upon the removal of the cyst and the  
remaining pituitous part of the thyroglossal tube. These  
cysts always occur in the midline and contain mucus with  
epithelial cells. Bruchigenetic cysts include those grouped  
as ranula submaxillary cysts and cervical cysts. It is prob-  
able that they all arise from embryonic remains of the  
cervical sinns. The persistent sinns may show as a fistula  
discharging on the surface of the neck along the anterior  
border of the sterno mastoid muscle. The cure of these cysts  
is a difficult and delicate surgical undertaking.

## 222 Primary Subungual Malignant Melanoblastoma

K SPECHT (*Deut Zeit f Chir* June 1927 p 390) who records an illustrative case states that this tumour which arises from the pigment cells of the nail bed only occurs on the thumb or great toe. The male sex is usually affected. An injury is followed—on the average in about a year's time—by the development of granulation tissue which resists all forms of treatment and remains stationary from six to twelve months. Pain at first is usually absent or only slight and then spontaneous lancinating pain occurs and the granulations which were formerly blood red assume a greyish hue and become converted into a nodule which is always covered with a thick layer of epidermis and never becomes ulcerated. The nodule rapidly increases in size and involves the whole thumb or great toe, the surrounding area becomes inflamed and within three to six months after formation of the tumour metastases form in the regional glands and later the lungs and brain. An early diagnosis is important, but is no easy

at first Specht thinks that every recurring growth of granulation tissue with chronic inflammatory reaction which shows no tendency to heal should be regarded with suspicion, especially if the granulation tissue becomes converted into a nodule with spontaneous dragging pain. A differential diagnosis must be made from chronic inflammation, tuberculosis, and primary chancic. The prognosis is unfavourable when once metastases in the glands have developed. Treatment should consist in amputation, but if the case is inoperable, rays should be tried. In Specht's case, which occurred in a man aged 43, the tumour developed nine months after he had run a splinter under the thumb nail. Amputation of the terminal phalanx was performed. No recurrence was observed at the end of nine months.

#### 223 Pain in the Heel due to Periostitis of the Os Calcis

L. HUSIED (*Ugeskrift for Læger*, July 28th, 1927, p. 676) has observed in recruits accustomed to a sedentary existence in civil life, and not used to the gymnastics and long marches of military service, a condition characterized by pain in one or—more seldom—both heels while walking or running. This pain became worse till the patients could no longer walk. On examination tenderness was always observed at the site of insertion of the Achilles tendon. In some cases, but not invariably, there was slight swelling of the soft tissues in the neighbourhood, and in no case was discoloration of the parts observed. In uncomplicated cases there was no tenderness of the bursa of the tendon, no swelling, tenderness, or crepitation about the tendon itself. There was no limitation of movement or pain on passive movement of the ankle, but pain could be elicited at the site of insertion of the tendon by walking, standing on the toes, or resisting passive dorsiflexion. Rest in bed for eight to ten days, supplemented by fomentations when the soft parts were swollen, effected a cure, and the author has had only one troublesome case of relapse. He draws attention to the widespread ignorance of this comparatively common cause of pain in the heel.

#### 224 Peritonitis Chronica Fibrosa Incapsulans

L. JOSI (*Centralblatt für Chirurgie*, July 2nd, 1927, p. 1689), who records an illustrative case in a boy, aged 16, on whom a successful operation was performed, states that only a few examples of this condition, which is sometimes known as "iced intestine" (*Zuckergrundstauung*), have been described. Most patients are males and the ages range from 13 to 55. As a rule only isolated parts of the gut are involved. The small intestine is always affected and sometimes the large intestine as well. The liver and spleen are occasionally implicated, but the pelvic organs almost always escape, the bladder and posterior abdominal wall were affected in only one case. The thickness of the covering may be as much as 2 cm., and the colour is an opaque white. Histological examination shows fibrous and granulation tissue undergoing hyaline degeneration. The symptoms of the disease are determined by the extent and position of the affected gut and the quality of the obstruction. As the peritonitis is chronic and develops without any exudation, the diagnosis of peritonitis is rarely made. If the whole of the intestinal tract is not involved, the affected part may be mistaken for a tumour or a cyst. Interference with the passage of the intestinal contents often gives rise to the erroneous diagnosis of organic intestinal obstruction, especially when a ray examination shows the site of the obstruction. Treatment is always surgical. The prognosis is not so unfavourable as might be expected.

## Therapeutics.

#### 225 Treatment of Heart Disease

R. L. LEVI and T. T. MACKIL (*Journal Amer. Med. Assoc.*, August 6th, 1927, p. 432) discuss the treatment of heart disease, and conclude that since digitalis by its direct action on the cardiac muscle increases the amplitude of ventricular contraction its main indication is found to be myocardial insufficiency. It is best administered by the mouth in pills, tablets, or capsules containing 12 grains of a standardized powdered leaf, an average total dose to reduce full therapeutic effect within from twenty-four to forty-eight hours being 22 grains in separate doses. For local administration the tincture is best, and onrham for intravenous or intra-arterial injection. Quinidine is useful in disorders of rhythm, especially auricular fibrillation, but care must be exercised in the choice of patient, suitable cases being those of recent onset with but slight cardiac enlargement and no valvular disease, or of fibrillation associated with a recent infection or hyperthyroidism. Its intravenous administration is said to be dangerous. While digitalis therapy generally causes diuresis

in cases of congestive heart failure the elimination of fluid may sometimes be facilitated by the additional use of such diuretic drugs as theophylline, theobromine, theobromine sodiumsalicylate, and novasurol, though this latter, because of its mercurial content, should only be used after the others have been given a thorough trial. P. D. WHITE (*ibid.*, p. 435) considers that the best results in cardiac treatment are frequently obtained by agents other than drugs—namely, physical and mental rest and recreation, graduated exercises, massage, climate, diet, physical procedures, psychotherapy, venesection, and surgery. Judgement is needed in the application of rest and recreation, since they may be abused by too prolonged or by insufficient use. The same applies to dieting, but, generally, small light meals at frequent intervals with restricted fluid intake, according to circumstances, is desirable. Cervical sympathectomy or paravertebral injection of alcohol into the spinal nerve ganglia for angina, paracentesis for serous or purulent pericardial effusion, and venesection for temporary cardiac relief, are among the surgical procedures which may be of value.

#### 226 Treatment of Enlarged Prostate by Diathermy

J. G. REVINSE (*Nederl. Lydschr. v. Geneesk.*, July 30th, 1927, p. 508) who records ten successful cases in patients aged from 64 to 84, claims the following advantages for diathermy in the treatment of prostatic hypertrophy. The method is by no means drastic and therefore the risk is slight, it can be performed painlessly after the intraurethral injection of novocain or tutocain. No bleeding occurs. The treatment can be controlled by the index finger. All forms of prostatic diseases which give rise to retention of the urine can be dealt with in this way. This procedure would probably obviate a considerable number of prostatectomies which would otherwise be necessary. When an operation cannot be performed owing to the bad general condition of the patient diathermy can be employed with success.

227 O. GRANT and J. R. STITES (*Urol. and Cut. Rev.*, July, 1927, p. 447), who record three illustrative cases, maintain that the treatment of chronic prostatitis by diathermy, though comparatively new and still in the experimental stage, has a very important place in urology, both medically and surgically. The types of patients most suitable for treatment by diathermy are (1) those who show signs of toxic absorption manifested by arthritis of varying intensity, (2) those who have acute exacerbations with chills and fever and no urological symptoms except cloudy urine, and are often treated for influenza, until their real trouble is recognized by examination of the urine at an insurance office, and (3) patients who complain of some urological disturbance such as "acid urine" or morning discharge. The more acute cases do best under palliative measures until the acute stage has subsided. As the result of diathermy the prostatic secretion is more easily and less painfully expressed, and pus is evacuated which has not been discovered by massage.

#### Crystalline Insulin

228 J. J. ABEL, E. M. K. GILLIN, C. A. ROUILLER, T. K. BELL, and O. WINTERSILINER (*Journal Pharm. and Exp. Ther.*, May, 1927, p. 65) report further progress in the elaboration of a simple method for the crystallization of insulin, previous reference to Abel's work in this connection appeared in our issue of April 10th, 1926 (p. 666). Commercial preparations of insulin undergo a process of iso electric precipitation. They are dissolved in dilute acetic acid and barium acetate is added. Impurities are precipitated in part with pyridine, and, on adjustment to the proper pH with ammonia, insulin crystallizes out. The evidence suggests that two different crystalline forms exist, identical in chemical composition, the empirical formula of the dehydrated product is  $C_{24}H_{38}O_{11}N_{14}S$ . Such information as there is relating to their chemical constitution tends to confirm the suggestions of other workers that insulin is a body of peptidic nature, which gives the Farly, Millon, biuret, and murexide reactions, the first two indicate the CO-NH linkage and the presence of free amino groups respectively. The crystalline preparation was shown to contain neither cystine nor cysteine in the free state. The substance is optically active, it is rapidly destroyed by alkali, and loss of activity always follows disturbance of the sulphur atom. The rabbit unit is in the neighbourhood of 40 per mg. (international standard), which indicates that, if the product be in really pure, insulin is far less potent than the oxytocic principle of the pituitary secretion, preparations of which known to be impure show a far greater degree of activity. The unitage of the product was, however, unaltered by two crystallizations from an aqueous medium and by recrystallization from an alcoholic aqueous buffer mixture. In a typical experiment 0.528 gram of crystalline iodine was obtained from 2 grams of a commercial product.

**229 Bismuth in the Treatment of Syphilis**  
O. I. MULLER (*Med. Journ. Ant. Leech*, July 20th, 1927, p. 103), in commenting favourably on the value of bismuth in the treatment of syphilis in adults, however, thinks the best results are not always obtainable by administering this alone. He finds it particularly useful in neurosyphilis and states that this metal is demonstrable in the nerve tissues in larger amounts than either arsenic or mercury. He reports six cases in which skin manifestations appeared while the patients were under intensive treatment with bismuth, in some of these the condition seemed to be definitely a form of bismuth dermatitis, and the substitution of other antisyphilitic remedies caused the disappearance of the skin lesion which included irritative erythematous macules on the arms and legs, eczematous patches on the hands, and soreness in the anal and perianal regions.

## Dermatology.

**220 Poikiloderma Atrophicum Vasculare**  
A. M. BOWMAN and F. C. CLARK (*Arch. Derm. & Syph.*, May 1927, p. 283), give details of a case of poikiloderma atrophicum vasculare and refer to eighteen cases reported previously in the literature. They conclude that three possible causes of this rare disorder deserve serious consideration—namely, exposure, infection, and endocrine disturbance. They add that the condition may possibly be of nervous origin and that the definite evidence of a distinct morbid process in the sympathetic ganglia seems to indicate that the atrophic changes are caused by lack of proper trophic stimuli from the sympathetic nervous system. The lesions of the skin are, however, not so easily explained on this supposition. The case reported by the present authors occurred in a man aged 39, who was weak and stunted from birth. His hands were severely frost-bitten at the age of 23 and soon afterwards the rash broke out on his face. Seven years later it spread to his body and became progressively more noticeable. He suffered much from chilblains. Granuloma appeared first on the fingers and then on the toes. Mental symptoms followed, and the joints became stiff. Thin spots were plum coloured and contained fine capillaries. They were situated in the tissues and not raised above the surface. Over the back there was an irregular distribution of patches. The weakness and stiffness increased and a cataract was removed from the left eye, but the patient died from acute cardiac decompensation after this operation.

**221 Granuloma Inguinale.**  
P. BROCKE BLAND (*Urol. and Cut. Rev.*, May, 1927, p. 293), who records an illustrative case, states that both sexes are almost equally prone to granuloma inguinale which is much commoner in the coloured than in the white race. The average age of the patients is 30. The disease commences by the formation of granules, which may increase and form nodules of the diameter of half an inch or more. These develop in the cutis, and as they increase in size they raise and stretch the overlying epidermis which gives way in places so that superficial ulceration results. The ulcerated surface gives rise to a profuse watery discharge and bleeds readily on the slightest provocation. In course of time the nodule is replaced by dense scar tissue which becomes irregularly pigmented. The disease usually appears in the neighbourhood of the genitals—in the female it invariably develops in the labia or in their immediate vicinity—and travels along the folds of skin until the groin, from one anterior superior iliac spine to the other are implicated. The skin over the pubis being most severely affected. The disease also follows the femoral labial folds finally involving the perineum as far as the coecum and sacrum. Sometimes it invades the urinary as well as the alimentary tract. In cases of long duration various lesions are seen such as papules, some of which are necrotic areas of necrosis and pigmented scars. Cases of pregnancy and labour complicated by granuloma inguinale, of which Bland reports an example are exceedingly rare.

**222 Dermatitis Produced by Balsam of Peru**  
C. L. CLIMPEY (*Arch. Derm. & Syph.*, July 1927, p. 44) reports a case of dermatitis produced by balsam of Peru which is infrequently used both for its stimulating property and as a component of ointment for the treatment of scabies. His patient was a steel worker aged 40 who had been burnt on the right arm and chest on March 22nd, 1925. The burns were of the first degree and since healing did not occur daily the ointment used was suspected. It was found experimentally that ointments containing phenol and balsam of Peru produced irritation the balsam ointment more so than the other. The

patient presented a picture of infectious eczematoid dermatitis. Wet compresses of potassium permanganate were used and the patient left hospital on May 16th greatly improved. The skin finally cleared rapidly after x-ray irradiation. Experiments were then performed to define the irritating ingredient in the ointment previously used. Small amounts of various ointments including one containing balsam of Peru were applied and covered with a gauze square the areas of application being widely separated. On the next day all dressings were in place except the one containing balsam of Peru which was to discomfort the patient had removed it, and the area showed erythema and vesication. The author cites the literature to show that more severe complications occasionally follow the use of this balsam.

**223 Impetigo Herpetiformis**  
F. WALTER (*Ann. de Derm. et de Syph.*, May, 1927, p. 257) reports two cases (one fatal) of this rather rare disease in pregnant women. He has collected about sixty similar cases with thirty one deaths. The disease is often associated with convulsive attacks as in the author's two cases although these sometimes may be slight. Walter thinks that the main cause is some disturbance of the endocrine glands. In the case of pregnancy associated with this affection the serum obtained from the blood of a healthy pregnant woman is said to be beneficial. In the author's second case this treatment caused the herpes to pass into a psoriasis like condition.

## Obstetrics and Gynaecology.

**224 Observational Use of Ergot and Pituitary Extract**  
A. BOURVILL and J. H. BURN (*Journ. Obstet. and Gynaecol. of the British Empire*, Summer Number 1927, p. 249) have investigated the action of drugs on the parturient uterus in the first, second, and third stages of labour. They recorded the intrauterine pressure and the work done by the uterus muscle by introducing a hollow rubber disc connected with a manometer about eight inches within the uterus. With regard to the separate ergot alkaloids—tyramine, histamine, and ergotamine (or ergotoxin)—they find that (1) tyramine in pharmacological doses has little effect and is without value in obstetrics; (2) histamine given subcutaneously in doses of 2 mg. leads to a quick powerful and transient rise of intrauterine pressure; (3) ergotamine in doses of 0.5 to 1 mg. hypodermically gives rise after a latent period of twenty to thirty minutes, to a prolonged increase of tone of myometrium. The practical conclusion drawn is that while none of the ergot alkaloids have a place in therapeutics before delivery of child and placenta it is possible that in post partum haemorrhage a combination of histamine and ergotamine may be of more value than pituitary extract. The liquid extract of ergot of the *British Pharmacopoeia* does not contain ergotamine and can therefore it is stated have no therapeutic effect. The authors are satisfied that an injection of two units of pituitary extract corresponding to 0.2 c.c. of most of the commercial extracts can be given with safety, in the absence of mechanical obstruction at any stage of labour, the least interval at which any dose can be usefully repeated is one hour. Such a small dose produces in the majority of cases an increase of tone and/or of rhythmic uterine contraction and if the dose is at least half diluted a sluggish labour may, with some confidence, be expected to be hastened.

**225 Torsion of the Fallopian Tubes**  
CAPAVEN (*La Gynecol.*, June 1927, p. 356) reports a case of torsion of the Fallopian tube in a woman aged 34 years who after taking some abortifacients suffered from uterine haemorrhage for seven days. A month later she took more abortifacients and sharp abdominal pains and vomiting followed. A slightly tender swelling was found in the lower epigastric region, the uterus was anteverted and a large mass filled Douglas's pouch. A diagnosis of ruptured tubal pregnancy with pelvic haematocoele was made. At the operation three days later the pouch of Douglas was found filled by a haematocoele with adhesions to the posterior uterine wall. A twisted Fallopian tube twisted twice at a point 3 or 4 cm. from the uterus, was removed with the ovary recovery was normal. The tube and ovary were filled with ordinary homogeneous blood clot but the peritoneal covering of the tube was normal without signs of chorionic villi or of old infection. The adnexa of the other side were normal except for slight congestion. CAPAVEN thinks that the formation of a pelvic haematocoele should have been diagnosed and states that in none of the recorded cases of torsion of healthy adnexa was a haematocoele mentioned although in one case blood was withdrawn by aspiration from Douglas's pouch.

and in another 300 c cm of blood stained serum was removed from the peritoneum. He adds that torsion may involve the tube only, or both tube and ovary, it may occur before puberty and in virgins. The condition has been diagnosed clinically as appendicitis, renal colic, ectopic gestation, and torsion of an ovarian pedicle. The etiology remains obscure, though it was possible in Caraven's case that the apical set up violent contractions of the tubo uterine musculature. Abnormal length and sinuosity of the tubes, combined with menstrual congestion, may be predisposing causes, to these may be added violent physical exercises, falls, and strains. Manciano states that by means of laparotomy it is possible to observe these spasmodic longitudinal and circular contractions, which may be subsequent to lesions of neighboring organs, or the patients may be subject to spasmodic philia. C. LEMORMANT (ibid., p 358) also describes a case of torsion of the Fallopian tube. The patient had had an attack of abdominal pain six months previously, which had subsided after a few days. A second sudden attack of pain localized in the hypogastrium without any haemorrhage brought the patient to hospital, where a diagnosis of haematocoele was made. The operation revealed a very swollen tube twisted three times upon itself. The tube was removed, but the ovary was left and recovery was uneventful. Histological examination revealed no pathological change in the tube.

### 236 Pregnancies during Amenorrhoea after X-ray Treatment of the Ovaries

ACCORDING to C. HOLTERMAN (Zentralbl. f. Gynak., August 13th, 1927, p 2091) Zaugemeister was the first to record a case in which after irradiation of the ovaries pregnancy ensued without an intervening return of menstruation. Holtermann describes the case of a woman, aged 35, who had suffered for over twenty years from pulmonary tuberculosis, at the age of 32 indications for unilateral ovarian castration by x-rays were found in an exacerbation of the pulmonary disease, accompanied by severe menorrhagia. To induce amenorrhoea a subsequent application to the other side of half the earlier dose was necessary. Three years later the patient, who had a contracted pelvis, was delivered by forceps of a dead but large and well formed foetus. A second conception followed within twelve months of the first, the new pregnancy terminated after artificial induction of premature labour in the birth of a live, healthy child, free from malformations. The patient had not menstruated since the application of x-rays six years previously.

## Pathology.

### 237 The Bactericidal Action of the Commoner Phenols

WITH the object of selecting germicides likely to be efficient as internal disinfectants, and of correlating chemical constitution with bactericidal power, J. F. CAIUS, B. P. B. NAIDU, and J. S. JANG (Indian Journ. of Med. Res., July, 1927, p 117) conducted a number of experiments, using *B. pestis* as the test organism. They cultivated the organisms in both containing definite amounts of the disinfectant, and determined the exact concentration necessary to prevent development, the four groups of substances so tested were the phenols, derivatives of phenols, compounds obtained by the condensation of two molecules of a phenol with one of phthalic anhydride and, lastly, the derivatives of fluorescein or resorcinolphthalein. It was found that solution in alkali either depressed or intensified the bactericidal power of monohydric phenols without any apparent cause, but generally enhanced that of the polyhydric phenols. A comparatively high activity was manifested by the following: quinol (1 in 432,000), microchlorine 220 soluble (1 in 76,800), catechol (1 in 48,000), alpha nitroso betanaphthol (1 in 25,600), tolhydroquinone (1 in 14,400), 2, 4 diamino phenol (1 in 12,800), carvacrol (1 in 11,200), 2, 4, 6 trichlorophenol (1 in 10,000). The authors state that as a class the phthalein dyes have a relatively small bactericidal value, and that microchlorine owes its activity to the labile mercury in its molecule.

### 238 Internal Secretion of the Ovary

L. BROUHA and H. SIMONNET (Bruxelles Med., August 14th, 1927, p 1317) report on the physiological properties of the liquid-follicular—in the Graafian follicles of the ovary, and state that it exerts a specific anabolic action on the female genital tract and on the mammary gland. The observations were made by injecting the follicular fluid or an extract of this fluid in olive oil into guinea pigs and rats of various sexual ages. It was found that in females before the age of puberty the fluid evokes uterine, vaginal, and mammary phenomena resembling those of puberty, accelerating the maturation and atresia of the follicle. In the adult female

it prolongs the oestral characters and produces a lasting hypertrophy of the uterus. In the adult castrated female the injection restored the phenomena of the physiological oestrus and also the morphological characters of the uterus and mamma. In the female during gestation the effect was found to vary with the period of pregnancy, it was without effect towards the end of the term, but in the initial periods it might bring about abortion. In the female during lactation it determined transient oestral phenomena, but did not influence the secretion of milk. The authors add that the follicular fluid *in vitro* can confer on the uterus removed from an animal, either before or after puberty, at the period of dioestral rest, the functional aspects of a uterus removed during the oestral period. It is also capable of giving to the resting uterus, by washing, a rhythm and power of contraction analogous to those of the uterus during oestrus.

### 239 The Reticular Endothelial System in Tuberculous Infection

ANNA SASSONE (Il Morgagni, July 17th, 1927, p 1121) has continued Goldman's study of the behaviour of the reticulo endothelial tissue in tuberculous infection, employing the method of vital staining by "puirulo" (bino d'isammina), certain cells which become stained are termed "pirophil", and those which do not "pirophobo". Guinea pigs were infected with tubercle bacilli and injected with puirulo (1 c cm of a 1 per cent solution per 100 grams of body weight) on alternate days until the sclerotics and skin became coloured. Later the animals were killed and preparations from the infected tissues were stained with safranin. The endothelial cells and the reticular cells of the mesenchyme are pirophil. In those cases where necrotic changes had not commenced the giant cells were not stained, but when degeneration had set in the infiltration of the stain was readily seen. Caseous substance showed very marked puirulo staining. The author concludes that the mesenchyme in the area attacked by the tubercle bacilli takes an active share in the formation of the tuberculous tissue, which is in part therefore, certainly of histogenic origin, the share taken by the mesenchyme is greater the more attenuated the action of the bacilli, so that in granulation tissue, which is really an anatomical pathological expression of modified bacterial action, almost all the cellular elements are mesenchymatous derivatives. Tuberculous tissue is intensely pirophil. The tuberculous giant cell is certainly not histogenic, only the epithelioid cells are of histogenic origin. The amount of mesenchymatous cells in a tubercle is an index of the activity of the organism in the tissue attacked. The mesenchyme is only able to react strongly to the tuberculous infection when this is attenuated, it is probable that the mesenchyme is important in the production of caseous substance.

### 240 The Pathogenicity of Filterable Forms of Tubercle Bacilli

ACCORDING to J. VALTIS (C. A. Soc. de Biologie, July 15th, 1927, p 477) if a filtrate of tuberculous material or of a culture of tubercle bacilli is injected subcutaneously into guinea pigs it is followed by the development of glandular lesions—particularly in the tracheo bronchial glands—characterized by a greater or less degree of enlargement, the glands never become caseous. On careful examination it is possible to find a few acid fast bacilli arranged singly or in small groups. Animals infected with tuberculous filtrates never develop a local lesion or focal adenitis, occasionally nodular lesions, generally discrete and often limited to the lung or spleen, may be observed. The tuberculin reaction is irregular and often fleeting. Valtis maintains that these findings cannot be explained on the assumption that a few tubercle bacilli succeed in getting through the filter. To test this assumption he inoculated a series of guinea pigs with very small doses of a virulent bovine strain, the actual number of bacilli injected he calculates as 4, 40, and 400. Those animals after a time reacted positively to tuberculin, and continued to do so till their death. At necropsy the typical picture of experimental tuberculosis was found—caseous adenitis and caseous nodular lesions in the organs. Proceeding still further, he tested the virulence of the acid fast bacilli found in the glandular lesions of animals that had been previously injected with tuberculous filtrates. A pregnant guinea pig received three injections of a filtrate of tuberculous ascitic fluid 10 weeks later she gave birth to three young, one of these was killed and was found to have an enlarged portal gland containing numerous acid fast bacilli. A part of this gland was ground up and injected into two fresh guinea pigs. One of these died two and a half months later with slightly enlarged tracheo bronchial glands containing acid fast bacilli, the other died three and a half months later without any lesions. The author therefore concludes that the acid fast bacilli derived from filterable forms of tubercle bacilli have no greater virulence than the forms themselves.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine.

### 241 Haematological and Clinical Aspects of Human Rabies

D. IONESCO and B. WALTER (Bull. et Mem. Soc. Med. des Hop. 19, 1927, p. 47) state that Babes in 1887 was the first to draw attention to the occurrence of a polymorphous nuclear leucocytosis in mad dogs and to its early development. Courmont and Lesieur confirmed these findings in 1888 and Sabrazes and Grilly saw a case of untreated human rabies with a predominant polymorphonuclear leucocytosis. Ionesco and Walter record their observations in five cases of human rabies in patients aged from 6 to 45. Their conclusions are as follows: (1) There is a shift to the right in respect of Leitch's formula or a general diminution of the peroxidases which increases during the course of the disease. (2) In one case there occurred in the prodromal stage changes in the blood consisting in leucocytosis, increase of the polymorphonuclear cells and absence of eosinophils and a rise in number of the red corpuscles probably due in part to respiratory inefficiency. (3) Pruritus is an early symptom but as the disease progresses it invariably becomes transformed into a feeling of burning or pain. It first localized at the site of the bite and subsequently generalized.

### 242 Anuria in Scarlet Fever

H. L. HIGGINS and W. J. GRAY (Inter. Journ. Dis. Child. June, 1927, p. 925) who record an illustrative case remark that anuria in scarlatinal nephritis is rare. In Dunham's case the anuria lasted fifty-one hours with recovery. Kohn reported a case with recovery after complete suppression of urine for five days. In Pisano's case no urine was excreted for two days but there was abundant sweating, there was no oedema. When urine was passed again it contained blood and albumin. Recovery was rapid. There are several cases of post-scarlatinal anuria on record in which the urine before and after the anuria seemed normal and contained no albumin or blood. In the present case, which occurred in a girl aged 3, nephritis set in on the sixth day of scarlet fever. Anuria which developed at once lasted seven and a quarter days and was not accompanied by any symptoms of uraemia. Treatment consisted in intravenous injections of hypertonic solutions (glucose 90 per cent, magnesium sulphate 2 per cent, and calcium chloride 0.2 per cent) to reduce the oedema presumably present in the kidney. The function of the kidney was in process of restoration when a streptococcus septicemia caused suppurative nephritis, otitis media, empyema and finally death.

### 243 Immunization against Tuberculosis

J. HEIMBECK (Norsk. Mag. f. Laegevid. June, 1927, p. 457) describes investigations since January 1924 into the incidence of positive and negative Pirquet reactions among probationer hospital nurses. From the beginning of 1924 to a date not specified in 1927 as many as 397 nurses were recruited and they were tested with concentrated old tuberculin in most cases during the first week of hospital service. In 189 cases the reaction was positive, in 208 it was negative. If most of the nurses had come from the country, this high proportion of negative reactions might not have seemed surprising but as many as 60 of 116 nurses coming from villages and as many as 66 of 148 coming from towns gave a negative reaction. The author remarks that the common assumptions that hardly any adult town dweller gives a negative reaction and that even as early as the 15th year from 70 to 80 per cent give a positive reaction are chiefly based on examinations in towns and schools and he suggests that between the end of the school age and the years about 20 an old infection contracted in childhood may have died out to such an extent that the Pirquet reaction becomes negative. The subsequent fate of the probationers showed that those whose reaction had been negative were at a grave disadvantage. During the three years since these tests were started as many as 43 of the 397 nurses developed some manifestation of tuberculosis and 40 of them had given a negative reaction on entering the hospital. Among the diseases counted as manifestations of tuberculosis was erythema nodosum of which there were 18 cases and the author justifies his claim that these were cases of tuberculosis by pointing out that in every case the patient gave a violently positive reaction to the Pirquet test when it was repeated after erythema nodosum had been diagnosed. Nearly all the nurses giving a negative

reaction as probationers became positive reactors during their sojourn in hospital. Thus of the 51 who gave a negative reaction in 1924 only one continued negative and only two persisted out of the batch of 72 negative reactors among the probationers of 1925. In 1926 the author began to immunize nurses who gave a negative Pirquet reaction by injecting small quantities of Calmette's BCG culture of attenuated tubercle bacilli under the skin. He preferred the subcutaneous to the peroral route on the assumption that the permeability of the digestive tract of adults was not so great as in infants, whom Calmette vaccinates by the mouth. He did, however, give P.C.G. by the mouth in three cases. Eighteen persons received subcutaneous injections the dose found most satisfactory being 0.05 mg. While a rather violent reaction followed the injection of 0.2 mg. under the skin of a healthy man with a positive reaction the administration of the vaccine to persons who were negative reactors proved on no very troublesome reaction but it made them positive reactors. During the time that had subsequently elapsed—the longest observation period being nine months—these persons have continued to give a positive reaction to the Pirquet test and the author claims accordingly, to have achieved so far what he set out to do.

### 244 Infective Coronary Thrombosis

G. HARCOURT, A. S. MCPHEID and N. B. GUY (Canadian Med. Assoc. Journ. July 1927, p. 750) report a case of infective coronary thrombosis with recovery from prolonged bacteriæmic phlebitis and symptoms of pulmonary embolism. The case presented the unusual features of multiple venous thromboses, involvement of the splenic vein produced a large splenic tumour with hyperleucocytosis together with blockage of the coronary arteries which suggested that the cardiac veins or arteries were also involved to the same general infection. The patient was a married woman subject to biliary attacks from childhood with an interval of freedom for ten years after marriage but with subsequent recurrence. She complained of severe epigastric pain with fever and slight jaundice and a tumour developed in the splenic area. The white blood count reached 40,000 to 60,000 per c.m.m. and a blood culture showed the presence of *Staphylococcus aureus*. At an operation the tumour mass was found to be the spleen limited in its movements by adhesions. The splenic vein was enormously dilated and filled with thrombus which extended upwards to the pancreatic veins. The spleen was removed and for the first three weeks the condition was but little changed, the white blood count remaining high and the blood-cultures of *Staphylococcus aureus*. Thrombosis of the left femoral vein followed and ten days later the right became involved. There were signs of emboli in the lungs which eventually cleared up though the white count remained high. One night she was suddenly awakened by agonizing anginal precordial and substernal pain causing collapse. She was almost pulseless for several hours, the cardiac area being enlarged and the sounds faint and associated with a distinct precordial rub which lasted for twenty-four hours. She rallied gradually from this attack and progressed favourably for several months but eventually died from heart failure two years after the onset of the illness. Examination of the spleen suggested Banti's disease, which the authors consider of the greatest interest in view of the many findings in the case. They suggest that the acute cardiac thrombosis of artery or vein was part of the general infectious process rather than an incident in connection with coronary arterio-sclerosis.

### 245 Gastric Achylia.

F. F. MARTINEZ (Paris Med., July 30, 1927, p. 65) draws attention to two groups of cases of gastric achylia associated with varying degrees of neurosis. The first, he thinks, constitutional or congenital and the second included cases in which the condition is acquired or neurogenic. He thinks that the occurrence of achylia as a congenital deficiency offers a large field for study, and suggests that inherited nervous instability may be the most important factor in its production. As an example of the first group the author cites the case of a woman whose mother and grandmother had died of gastric cancer after suffering for many years from attacks of diarrhoea and abdominal pain. The patient who was very well developed in intellect but of a nervous disposition had suffered all her life from hemicolic diarrhoea, and was found to have achylia. She died eventually of gastric cancer. She had six children two of whom died

young, of the remainder, three female and one male, two inherited to some degree her higher mental qualities, but all had acholohydria, suffered from diarrhoea and dyspepsia, and were neurotic, two in a very marked degree. Seven of the thirteen children of these four persons are in normal physical health, though one has acholohydria without symptoms. Of the remaining six, one is an imbecile and four suffer from various physical abnormalities not associated with the digestive tract, one of the latter has acholohydria, and another has acholohydria associated with severe digestive disturbance. As an example of the second group of gastric rehylla, Martinez describes the case of a married woman aged 56, with acholohydria and severe digestive disturbance, her father had died of gastric cancer, and two uncles had suffered for many years from digestive troubles. Two of her three daughters are hysterical to a marked degree, the third is highly strung and subject to acute crises of digestive discomfort on the slightest variation from a stilet diet. All three are known to have acholohydria. The author suggests that the inefficiency of the gastric mucosa in such groups of familial acholohydria associated in all three cases with diminution of the gastric ferments as well as of hydrochloric acid, may be produced by interference with the normal vagal tones, and emphasizes the need for further consideration of the subject.

#### 246 The Etiology of Cardiac Extrasystoles

ACCORDING to K. T. MICHAELI and M. L. SOLITERNAN (*Arch des Mal du Cœur*, August, 1927, p. 540) cardiac extrasystoles into two types—the functional (toxic or nervous) and the organic—though the lack of an exact pathology, the power of certain toxins to provoke these conditions and the results of animal experiments force him to conclude that organic extrasystoles have probably a functional origin. Vaquez states that extrasystoles should arouse suspicion of alterations in the cardiac structure. Ternovski and Mohilnitsky found no relation between a modification in the vagus and sympathetic systems and the appearance of an extrasystole. By stimulating the peripheral end of the vagus with an inductive current, Pleinow caused a typical extrasystole, and Lewis, employing the same method, noted an increase in the excitability of the muscles with a tendency to fibrillation. François Franck in 1882, and Delio ten years later, paralyse the action of the vagus on the heart by subcutaneous injections of atropine sulphate. Eppinger and Hess, Danilopolin, and others have employed intravenous injections of the drug, thereby avoiding errors resulting from differences in the absorption or possible decomposition of the atropine in the cellular tissue. By the injection of larger doses in ten patients the present authors obtained a more prolonged action on the vagus thus allowing closer study of the rhythm alterations. In all cases the extrasystole disappeared after administration of atropine. Some of the patients suffered from organic cardiac lesions, the others showed no organic trouble of the cardiovascular system. The doses employed were from 15 to 36 mg., and the arrhythmia disappeared not only when the rhythm was rapid, but also when it was insignificant, and even in periods of bradycardia. They add that the question is not yet solved whether the cessation of extrasystoles under the influence of atropine is due to an interruption in the transmission of excitations in the vagus and in the cardiac neuro-muscular time or to the exclusion of the nerve nodes and fibres of the primordium tissue of the heart. From their observations the authors conclude that the only causes of extrasystoles are functional and not anatomical, and that the tone of the vegetative nervous system is a great factor in heterotopic cardiac rhythm.

#### 247 Diagnosis of Epidemic Encephalitis

R. FLOYD and J. F. LONDON (*Med Journ and Record*, July 20th, 1927, p. 68) give notes of cases with autopsy findings to illustrate the difficulty of distinguishing epidemic encephalitis from tuberculous meningitis and ependymitis, solitary tubercles of the brain, dilated lateral ventricles, cerebral softening from general sepsis, meningismus with pneumonia, intracranial pal haemorrhages in status lymphaticus, ruptured cerebral aneurysm within the skull, intracranial bleeding from internal haemorrhagic pachymeningitis, encephalitis in pre-epidemic period, haemorrhagic encephalitis, and polio myelo encephalitis, all of which gave rise to symptoms easily mistaken for epidemic encephalitis. The authors summarize such conditions under the grouping of (1) inflammatory lesions of the brain tissue, pia mater, or ependyma; (2) non-inflammatory primary vascular lesions of haemorrhage or arterio-sclerotic stenosis; (3) intracranial tumours; and (4) conditions causing symptoms without typical lesions such as intoxication, ischaemia from increased intracranial pressure, and epilepsy usually. They discuss the differential diagnosis in such cases, but admit that the nature of the illness is often only made clear at the necropsy.

## Surgery.

#### 248 Spondylolisthesis

ACCORDING to T. H. ALBRE (*Journal Bone and Joint Surg*, July, 1927, p. 427) this condition, usually associated with pregnancy, has been found by radiological examination to be quite as common in men as in women. Spondylolisthesis is a forward displacement of the whole spinal column in relation to the fifth lumbar vertebra and sacrum. There is an acute or subluxation of the fourth or fifth lumbar vertebra in the sacrum. Trauma is the primary cause, although there may be predisposing congenital factors. About two hundred cases have been recorded. The symptoms are mild and usually appear late. Pain is sometimes present, but equilibrium is much disturbed and results in faulty carriage, nerve disturbances of the legs may be present. The only satisfactory treatment is the immobilizing spine operation. Albrec records eight cases in which the results of operation were most gratifying.

#### 249 Acute and Chronic Pancreatitis

T. S. CULLEN and J. FRIDENWALD (*Arch Surg*, July, 1927, p. 1) consider that the difficulty in diagnosing many pancreatic conditions depends on the facts that the pancreas is inaccessible to palpation, its secretion cannot be obtained for examination and the symptoms may be masked by other disorders of the digestive system. In acute pancreatitis the advisability of operation, owing to the great risk entailed, has not yet been definitely estimated. Many surgeons consider it best to delay till the shock has somewhat subsided. When the disease has progressed to the gangrenous and suppurative stages speedy operation is indicated. Chronic pancreatitis is often associated with cholelithiasis and cholecystitis. Chronic dyspepsia with epigastric pain, nausea, vomiting and emaciation are the common symptoms of this disease. The stools are bulky and contain undigested fat and protein. Early removal of gall stones is a wise preventive measure, while in established cases effective drainage of the biliary passage is the essential line of treatment.

#### 250 Association of Tuberculosis and Cancer

T. HARBITZ (*Norsk Mag f Lægevid*, July, 1927, p. 572) records four cases of the association of tuberculosis and cancer in the digestive tract. The first case was that of a man, aged 68, who died with symptoms of cancer of the stomach with metastases in the peritoneum, liver, and spleen. The necropsy showed an ulcer in the pyloric region, the border of which had the structure of an adenocarcinoma, while the base was tuberculous, the nodules in the liver, spleen, and peritoneum were also of a tuberculous nature. The next two patients were a man aged 28 and a woman aged 30 both of whom had tumours in the ileo-caecal region, in which tuberculous and cancerous tissues were intimately mixed, the tuberculosis being primary and the cancer secondary. In the fourth case the association of tuberculosis and cancer in the oesophagus was only a coincidence. Harbitz has also seen cancer associated with tuberculosis in the lymphatic glands of the breast, uterus, and the skin in the form of lupus carcinomata, where tuberculosis was probably the primary process and gave rise to the cancer.

#### 251 Adolescent Gastric Carcinoma

C. HAMMESFAHR (*Zentralbl f Chir*, July 23rd, 1927, p. 1864) describes the case of a youth of 18 who had a retrocolic gastro-enterostomy performed for pyloric ulcer after symptoms of duodenal ulcer with pyloric stenosis lasting a year and a half. At the operation a conical ulcer, measuring 4 cm in diameter and 2 cm in depth, was found, this was adherent to the adjacent gastric wall, which was pressed into the ulcer cavity. The gall bladder and liver appeared to be healthy and no enlarged glands were found. The stomach was large and atonic. The wound healed by first intention, the abdomen was flaccid with slight tenderness on pressure. Eighteen months later the patient was admitted to a medical ward for severe jaundice. He said that from the date of the operation he had felt well and had returned to work, but a sense of weight in the abdomen persisted until the onset of jaundice. He had slight pain and more or less the urine was free from albumin, but contained 1 per cent sugar, bilirubin was present, but the liver and spleen were not enlarged. In the epigastrium there was a hard nodular mass as large as a fist. Radiological investigation showed normal diaphragm movements and normal thoracic viscera. The stomach emptied itself very quickly (two and a half hours), though the uterine opening, but there was very deficient filling along the lesser curvature, while in the large there were numerous sharply defined shadows (metastases). An exploratory incision was made and a large amount of bile stained fluid escaped. The entire stomach and duodenum were found embedded in a hard scirrhous carcinoma with

adenomatous masses. The patient died six days later. The author comments on the rarity of cancer following a history of duodenal ulcer in a patient aged 19. He also describes the case of a man aged 37, on whom he performed a radical pyloric resection of an ulcer in 1924. There was no evidence of suspicion of cancer, but histological examination showed carcinoma degeneration of the edges of the ulcer. The resection was performed through sound tissue, and the lymph glands were apparently healthy. For two years the patient appeared to be cured, but then he complained of nocturnal vomiting and a sense of weight. An exploratory incision showed the stomach wall studded with small metastases with a harder elastic mass in the pyloric region. The peritoneal cavity was also covered with numerous metastatic nodules. Recently the author has been content to perform gastric gastrostomy alone as a preliminary operation in the case of debilitated patients in whom a simultaneous resection would prove too serious an undertaking.

**252. Surgical Treatment of Exophthalmic Goitre**  
H. LINDA (*Brit Med J*, July 23rd 1927, p. 997) advocates early operation in cases of exophthalmic goitre. He believes that severe cases with pronounced nervous symptoms are commoner than before the war, and are often allowed to drift on for months or years under medical or x-ray treatment until by the time they reach the surgeon they are fit from being in the most favourable condition for operation. Cases unsuitable for the surgeon are either the very mild ones or those with a very high pulse rate and marked nervous symptoms. Certain patients also exhibit actual mental disturbance and for them operation is contraindicated. No operation should be undertaken without preliminary preparation of the patient who must remain strictly in bed for at least a fortnight while the pulse is carefully watched. Digitalis is often given, and seems to have a definite effect in slowing the pulse rate; the effect is heightened if sodium phosphate is given with it. Landau thinks that the patient should be kept in ignorance of the approaching operation until the last possible moment. Open ether anaesthesia is preferable to the local method formerly employed. Although the mortality is slightly increased the type of case treated is much more severe than formerly. Of patients treated by operation 61.9 per cent were reckoned completely cured and were able to return to their occupations often far more quickly than where conservative methods had been used in treatment.

## Therapeutics

**253. A Ketogenic Diet in Epilepsy**  
H. F. HELMHOLTZ (*Journ Amer Med Assoc*, June 26th 1927, p. 2023) since 1922 has given children with idiopathic epilepsy a diet sufficiently high in fat to produce ketosis as manifested by diacetic acid in the urine. Originally the diet was tried in order to maintain the ketosis which was possibly responsible for the good therapeutic effect of starvation, but it was soon found to have a more definitely curative effect than starvation. In 91 patients who had been dieted sufficiently long to give a clear idea of the effect of the ketosis on the number and severity of the convulsive seizures the results were as follows: 29 (31 per cent) were freed from attacks and 20 (23 per cent) were considerably improved so that 54 per cent were definitely benefited by the ketogenic diet. Although 42 patients (46 per cent) received no permanent benefit, many of them were improved temporarily.

**254. Thallium Treatment of Ringworm and Favus**  
A. DOSTROVSKY (*Dermatol Woch*, May 28th 1927, p. 729) reports the successful use of thallium in 20 cases of ringworm and 2 cases of favus. Langer's method of administration and dosage was followed: 8 mg of thallium acetate per kilo of body weight being given in warm (boiled) water flavoured with a little syrupus aurantii. The water was free from iodine and contained the normal percentage of chlorides. All the children were examined in the pediatric department before treatment. The majority appeared to be normal but one child had spina bifida ocellita, a second had heart disease and a third had tuberculous peribronchial glands; the last two were quite tolerant of thallium. The children ranged in age from 2½ to 12 years; in 4 cases there had been recurrences after x-ray treatment. As a rule the hair could be removed easily and painlessly seven days after administration of thallium, after about nineteen days the hair fell out painlessly and about the twenty-fifth day came again about eight days after completion of epilation. To promote this active antiparasitic treatment was given at short intervals. Dostrovsky found that it was absolutely necessary to apportion the dose accurately to the body weight and not to the child's age. All the children lost weight and in every case

follicular dermatitis of the scalp occurred. In 5 cases there was some systemic disturbance two or three weeks after the administration of thallium, in 2 cases these symptoms disappeared after ten days, but in 3 others they persisted for six weeks. The author states that children who are below the normal in weight, even if otherwise healthy, should receive minimal doses of thallium. There was no evidence of permanent retention of thallium in the system but in 3 cases it was present in the urine for twenty-five, twenty-six, and twenty-seven days respectively. Thallium was not found in the blood or hair. Dostrovsky concludes that thallium is a valuable remedy for ringworm and favus in children, but it should not be given when renal lesions are present, nor when the patient is definitely under weight.

**255. Parenteral Alcohol Therapy**  
B. PITRIGLI (*L'et and Clin*, June 1927, p. 354) states that one of the principal groups of conditions in which parenteral alcohol therapy is indicated consists of various forms of circumscribed inflammation of an acute or subacute character—namely trichophytia profunda, boils, small phlegmonous infiltrations, infiltration of the sweat glands, mastitis, lymphangitis, hidradenoma, deep-seated nodules in scrofulous and rosacea. Britholmists in general bubo infiltration following intravenous injection of salvarsan or x-ray burn, tonsillar abscess and syngo erysipelas in man. The chief indication for the employment of parenteral alcohol therapy is an acute or subacute inflammatory process occurring more or less deeply in the tissue. Spethoff rarely exceeds a dose of 0.1 c.c. of absolute alcohol. The effects of the injection are shown by a very rapid cessation of pain and usually in a prompt softening which accelerates the healing process. In cases not ending in suppuration accelerated absorption occurs. If a repetition of the injection is necessary, it need not be performed before a week unless the action is insufficient or absent in which case a second injection may be given after three days. In infants injections of 0.02 to 0.03 c.c. of alcohol are given in 0.2 to 0.3 c.c. of sterile water. In adults the dose of alcohol is diluted in the syringe up to 1 c.c. with sterile water. Intraluted injections are borne without any reaction.

**256. Treatment of Pruritus in Children**  
B. DOPNIKOFF (*Monatsschr f Kinderheilk*, July 1927, p. 97) states that while there is no specific suitable for all cases, the best results are to be obtained by a combination of general and local treatment. In severe cases during the first few days the children should be wrapped in bandages and edatives administered especially chloral hydrate and bromurel. Occasionally a good effect is obtained with bromide but this is by no means the rule and relatively large doses are required. The sovereign remedy in acute and chronic infantile eczema is amyl nitrite in large doses which are well borne. In strophulus good effects are sometimes obtained by calcium preparations but more rapid and lasting results are derived from colloidal substances—especially human serum. Atropine has no good effect on the pruritus. The best local results are to be obtained from kamamel oil ointment with the addition of a little anaesthetic and novocain. In strophulus sulphur baths bring relief. In neurotic dermatosis and in strophulus change of environment is indicated and attention should always be given to the hygienic and psychological condition.

**257. Treatment of Hay Fever**  
As the result of a careful study of 980 cases A. VAN DER VEER, J. P. A. COOKE and W. C. SPAIN (*Amer Journ Med Sci*, July 1927, p. 101) distinguish three clinical forms of hay fever: the "pruritic" lasting from early April until early June, the early form from mid-May to the end of July and the late form from mid-August to frost. The last form though prevalent in America is practically unknown in Europe. The specific cause of hay fever is pollen derived either from trees or grasses and if the parent plants are closely related species of the same genus treatment with one pollen will protect against all. Thus the authors use timothy grass pollen for all grass cases. The method of preparation and standardizing the various pollen extracts is described. These extracts keep for a year in an ice box, and are used both for testing and treating. In testing for the specific pollen to which the patient is sensitive the intradermal is preferred to the scratch method and extracts containing 0.001 mg. nitrogen to the cubic centimetre are injected. Six of these tests may be performed at once on the outer surface of the upper arm and three series of such tests may be done at each skin test minutes being allowed to elapse between each series. When the specific pollen or pollens have been determined by positive reactions further skin tests with 0.0001 and 0.001 mg. solutions are made and ophthalmic tests with the 0.001 mg. solution are made to ascertain the degree of sensitiveness upon which dosage depends. Prophylactic treatment is the

method of choice, and should be commenced about ten weeks before the season opens. The maximum dose should be reached just before the season, and repeated at five to seven day intervals until the pollen disappears from the air, twenty injections being usually needed. Phylactic treatment is less satisfactory. In this case the first dose is repeated on three successive days, and larger doses given at gradually lengthened intervals. Local reactions ordinarily cause little discomfort and disappear in twenty-four hours. Constitutional reactions are more serious, and usually occur either from the injection of too large a dose, accidental injection into a vein, or from a change to a fresher and more powerful extract. Immunity, partial or complete, lasts for one or two years. In order to obtain a permanent cure monthly injections are advised throughout the year after the conclusion of the treatment, the maximum dose being administered each time. The authors report great success from this method, and have found it beneficial also in cases of pollen asthma.

### 258 Administration of Intracardial Injections

L. GOHRBRANDT (*Deut. Zeit. f. Chir.*, July, 1927, p. 28) considers that intracardial injection may be valuable in certain cases as a last resort, using 1 to 1½ c.c. of the standard solution of adrenalin diluted with 3 c.c. of physiological salt solution. When the heart is still beating the procedure is not free from danger and may cause injury to the cardiac wall and haemorrhage into the pericardium, intravenous injection, which has a similar but slower action, is therefore more usually employed. He thinks that intra and pericardial injections are too difficult, and, owing to the anatomical relations, more remote in their results. Injection into the auricle is not advised owing to its difficulty and the proximity of the site pierced to the excitatory system, moreover, adrenalin acts most strongly on the nervous apparatus of the heart when injected into the right auricle or right auricular appendix. Injection into the myocardium of the ventricle is considered preferable, since the mechanical stimulus is greater and the adrenalin is more rapidly distributed, but by intraventricular injection the area of the adrenalin stimulation of the nerve endings is wider, and also the site for the operation is easier to select. The result produced is said to be equally effective whether the injection is made into the right or the left ventricle. The influence on the nerve endings by right-sided injection is slightly later, but the injection is easier and its performance is more sure. The point of insertion of the needle is at the left sternal margin in the fourth or fifth costal space. To avoid pneumothorax the puncture should be made with a filled syringe. The injection should be given as soon as possible after cessation of the heart beat, ten to fifteen minutes may elapse before irreparable damage has been caused to the brain.

## Anaesthetics.

### 259 Choice of Anaesthetic in Thyroid Surgery

A. F. RENNEKER (*Amer. Journ. Surg.*, May, 1927, p. 431) reports a series of 4,000 operations on the thyroid gland during the last ten years under various forms of anaesthesia. In about the first 500 cases local anaesthesia was obtained by injecting a solution of 0.5 per cent. novocain, to which adrenalin had been added in the proportion of eight drops to the ounce. Although division of the skin, muscles, and capsule was satisfactorily accomplished, it was found that discomfort, and even faint, accompanied the raising of the gland from its bed and the stripping back of the capsule. Moreover, physical shock was occasioned and the operation was rendered long. Local infiltration associated with nitrous oxide gas and light ether anaesthesia was then tried and found more satisfactory. The induction was rapid, only a small amount of ether was used, the patient was usually conscious before leaving the operating table, and the stage of recovery was seldom more stormy than under local anaesthesia. Renneker has come to the conclusion, however, that a combination of nitrous oxide with oxygen is the most suitable anaesthetic for thyroidectomy. He tried ethylene, but discontinued it owing to the unpleasant odour and tendency to increased haemorrhage and delayed recovery. He recommends the preliminary employment of hypnotics and local anaesthetics, and emphasizes the importance of avoiding cyanosis during induction. He states that in his series of cases only one death occurred on the operating table, in this case the jugular vein was injured and death was due to embolism.

### 260 Spinal Anaesthesia with Cocaine

J. R. WELLS (*Annals of Surgery*, May, 1927, p. 757) reports successful results from the employment of spinal anaesthesia induced by anhydrous cocaine in 557 patients. He withdraws 25 c.c. of spinal fluid and injects a measured amount into an amber glass ampoule containing dried crystals of anhydrous

cocaine. The crystals dissolve instantly and the specific gravity of the fluid is unchanged. Each cubic centimetre of the solution is made to contain 0.01 gram of cocaine, and sufficient is reinjected into the spinal canal to produce anaesthesia for the duration required. Wells states that 0.01 gram of cocaine results in a period of anaesthesia of twenty minutes, 0.015 of forty-five minutes, 0.02 of one hour and fifteen minutes, 0.025 of one hour and fifty minutes, and 0.03 of two hours and thirty minutes. Most of the operations were below the level of the umbilicus, they included seven gall bladder cases, three rib resections, one major thoracoplasty, one compound fracture of the inferior maxilla, one scalp lipoma, and two trophimings. With the exception of thirty-two cases all of the patients, in the opinion of the operating surgeon, were unfit for any other form of anaesthesia, and included chronic alcoholics, drug addicts, advanced cardiac and pulmonary cases, and all types of arterio-sclerosis. The author adds that low blood pressure constitutes the only contraindication for this form of spinal anaesthesia, apart from spinal syphilis, tumours of the brain and cord, and local suppurative processes. Anhydrous cocaine has, however, a sudden profound and depressing effect on the systolic and diastolic pressures, but this was treated by the use of such remedies as caffeine, strychnine, pituitrin, ergot, and adrenalin, a moderate dose of the last being given to every patient immediately after the spinal injection.

### 261 Ethylene and Oxygen Anaesthesia.

G. L. LILLIES (*Med. Journ. of Australia*, April 23rd, 1927, p. 601) strongly recommends the use of a mixture of ethylene and oxygen for anaesthetic purposes. He usually commences with 80 parts of ethylene to 10 parts of oxygen, and increases the oxygen relatively according to the colour of the patient and the depth of the anaesthesia required. In the more robust patients he finds it often necessary to give a little ether with the gas during the early stages of abdominal section, and occasionally for closure of the wound. He finds that a preliminary injection of one-sixth of a grain of morphine is beneficial. Induction is said to be always quick and the odour of the gas is not noticed by the patient. Consciousness is lost after five or six inhalations, but complete saturation is not obtained for ten to fifteen minutes, so that it is inadvisable for the surgeon to commence operating earlier. Recovery is very rapid, and, therefore, the administration must be continued until the last stitch has been inserted. Post-anaesthetic vomiting is rare. Lillies has now given ethylene on 100 occasions, and thinks the only contraindication to its use is inflammability, which prevents its employment when a cautery is to be used. He emphasizes the importance of co-operation between the surgeon and the anaesthetist, and mentions that at first failures may occur in the induction of anaesthesia, this will disappear with increased skill. He has obtained good results in the surgery of the upper abdomen and in genito-urinary conditions. He reports three cases of death occurring during the administration of ethylene, two of the patients being moribund before the operation was commenced, while in the third—a man aged 70—there was regurgitation from the stomach, with inhalation of the gastric contents, causing asphyxia associated with cerebral haemorrhage.

### 262 Ephedrine in Spinal Anaesthesia

ACCORDING to N. F. OCKERBLAD and T. G. DILLON (*Journ. Amer. Med. Assoc.*, April 9th, 1927, p. 1135) ephedrine is of great practical value in spinal anaesthesia, in twenty-four cases uniformly good results were obtained in combating the marked fall in blood pressure which often occurs during and after such anaesthesia. Then procedure was as follows. The blood pressure having been first ascertained 10 c.c. of spinal fluid was withdrawn, 5 c.c. of which was discarded. From 125 to 200 mg. of sterile procaine hydrochloride crystals were dissolved in the remaining 5 c.c., which was then returned to the subdural space. The blood pressure reading was noted every ten minutes, and, when it had fallen by 10 per cent., 0.1 gram of ephedrine was given subcutaneously or orally. No untoward results were noted. The drug was administered before the systolic pressure dropped below 100 mm. Hg, and it was found preferable to endeavour to prevent the drop in pressure rather than let it fall too low, since the rise from levels below a systolic pressure was rather retarded. An increase in the pulse rate was noted, and it was found that the amount of procaine hydrochloride used for anaesthesia bore some relation to the rapidity and seriousness of the fall in pressure, and that in healthy young persons the fall was not so marked as in older and more feeble patients. The authors conclude that although in spinal anaesthesia there is a dangerous fall in both systolic and diastolic pressure the right amount of arterial tension can be restored by either the subcutaneous or oral administration of ephedrine. When given orally its action was found to be delayed, but it markedly increased the blood pressure.

## Obstetrics and Gynaecology.

### 263. Radical Treatment of Advanced Carcinoma of the Cervix

From a consideration of ninety-seven cases of inoperable advanced carcinoma of the cervix G. I. STRICKLAND (*Lancet* 1927 p 231) concludes that radium is a most potent palliative although only in a small proportion of cases a curative agent. Hemorrhages stop usually or are controlled and discharge ceases, as a rule more or less completely for a time. The pain is in most cases, less affected than the bleeding, and discharge. There is no evidence that radium properly applied predisposes to distant formation. The technique recommended is the introduction of 150 to 170 mg. of radium partly in the cervical canal and partly into the external parts of the growth when the needles are left in position by firm packing for twenty-four hours. Further applications depend on the subsequent clinical course. General anesthesia is employed and a preliminary vaginal douche is useful in cleansing the tumour and washing away discharge. The application is preceded by passage of a sound through the cervix and internal os—a small pyrometry (usually unneeded) is occasionally found and contraindicates radiotherapy for the time. The radium is inserted without previous scraping of the growth which interferes with vision and may dislodge the neoplasm. After radiation an x-ray examination of the pelvis ensures that no tube has become displaced into the vagina when a distal might be produced. The patient is instructed to douche the vagina night and morning using the enema three weeks as shown by Hayward Pouch, adhesive vaginalitis is thereby prevented. Contraindications to the use of radium are: (1) severe anaemia with an erythrocyte count below three million; (2) a foul-sloping surface of the carcinoma; (3) pyometra; (4) the presence of inflamed uterine appendages; (5) distant formation. Radium applications may be given later in the first group of cases after treatment by rest administration of iron and salines and, if necessary, blood transfusions in the third group they may follow a course of douching and repeated swabbing with iodized phenol.

### 264. Early Tuberculous Disease Causing Tubal Rupture

R. H. ULLMAN (*Centralblatt für Gynäkologie* August 6th 1927 p 2032) records the case of an apparently healthy woman aged 20 who fifteen months after normal delivery was admitted to hospital with grave signs of acute metapelite haemorrhage. Resistance and tenderness were detected in the left fornix and since abdominal puncture revealed the presence of fluid blood a diagnosis of ruptured tubal pregnancy was made. Microscopical examination of the left tube after its removal at laparotomy showed early tubercles in the wall of the tube near the rupture. The cause of the rupture is ascribed to tuberculous disease directly and not to tubal gestation of which the disease might have been a predisposing cause because (1) the patient had menstruated regularly until seventeen days before her illness; (2) colostrum was absent from both breasts; (3) the uterus was neither enlarged nor soft; (4) a corpus uterini of pregnancy could not be recognized in either ovary; and (5) histologically no sign of chorionic cells or of decidua reaction could be demonstrated in the excised tube. Thorough investigation of the patient's other organs including an x-ray examination of the chest failed to disclose an extra-uterine primary tuberculous focus.

### 265. Pituitrin in Labour

E. HATCH (*Lancet* 1927 p 456) traces historically the development of pituitrin in labour showing how in recent years a very definite movement has been started in favour of banning the drug altogether. The alleged practice of giving pituitrin before it has been ascertained that labour has really begun and without determination of the presentation may be partly responsible for this reaction. Hatch gives details of six cases of uterine rupture in five of which he holds pituitrin responsible. Among about 25,000 consecutive deliveries at the Rigshospitalet in Copenhagen there were ten cases of rupture of the uterus for half of which pituitrin was responsible. Hystero-graphic investigations have shown that the uterus does not completely relax in the intervals between the pains and this lack of complete relaxation entails danger particularly for the infant. In 1912 pituitrin was given in 8 to 9 per cent of all the confinements. From this year to 1917 there was a decline in its use which in both 1917 and 1918 amounted to only just over 2 per cent. In 1922 the percentage rose to be again 7 and 8 as the result of the introduction of much smaller doses but by 1925 it had again fallen below 5. From the latter part of 1911 to the present time pituitrin or some similar preparation was given in 1.05 per cent of 23,750 confinements—that is, in 4 per cent of the

total. In 110 cases the drug was used to hasten labour as the membranes had been ruptured in cases of placenta previa and in 74 cases of induced premature labour after dilatation and rupture of the membranes. It was given in 34 cases of too early detachment of the placenta, and in 475 uncomplicated cases of uterine inertia. A former indication, which the author now regards as a definite contra-indication, is threatened intraventricular asphyxia. Of the 47 cases in which the drug was employed for this condition only about half terminated in spontaneous birth in the remainder labour had to be terminated artificially. In view of the variations in the potency of the various preparations and of different combinations of the same preparation and of the great difference in susceptibility of various patients the author recommends small doses. Only after rupture of the membranes in placenta previa does he employ full doses. He now usually gives 0.2 ccm of pituitrin and in some cases has reduced the dose to 0.1 ccm. It has been demonstrated in this hospital that in most cases 0.2 ccm is as effective as 0.5 ccm. Should it not be so another injection can be given after one or more hours. Even with this cautious dosage accidents may occur and the medical attendant should always have ready at hand a supply of chloroform, ethyl chloride, morphine, or ether to counteract a too stormy labour.

### 266. Retention Cyst of Bartholin's Gland

J. L. HENROTAY (*La Gynécologie* June 1927 p 365) describes the case of a woman, aged 38 who was seven and a half months pregnant and who had a retention cyst of the right Bartholin's gland as large as an orange. On excising the cyst there was very profuse haemorrhage from the injured corpus cavernosum clitoridis and the vaginal bulb necessitating ligatures on mass of the bleeding tissue. The labium majus was reconstructed by approximation of the edges of the incision. Henrotay concluded that in a similar case it would be better to aspirate the cyst at the commencement and to excise it after delivery. Schoelcher has removed a suppurating cyst of the gland without difficulty during the fifth month of pregnancy to prevent puerperal infection. The confinement at term was normal. Pozzi has suggested aspiration of the cyst and subsequent injection of warm paraffin wax on cooling more complete dissection of the cyst is permitted.

### 267. The Heart during Pregnancy

From x-ray observations by the orthodiagraphical method F. CLAUSSER (*Annals of Obstetrics and Gynecology* April 30th 1927 p 173) concludes that in many cases the heart presents an increase of volume during pregnancy so that three out of five women at term have cardiac enlargement. This becomes appreciable clinically during the second half of gestation and augments rapidly during the last months. The lengthening during pregnancy of the longitudinal diameter of the heart shows that its enlargement is not in apparent due to ascent of the diaphragm—but real. The right ventricle participates to a greater extent than the left. Cardiac enlargement is due to two contemporaneous factors varying in intensity from case to case—a dilatation which is a physiological adaptation to the increased blood volume during pregnancy and a secondary myocardial hypertrophy. The changes incidental to pregnancy which are brought about in the lesser circulation and the alterations in arterial venous and capillary systemic circulation are rapidly compensated the only significant factor affecting the heart is the increased mass of the blood. As a rule the heart at term shows greater enlargement in the case of multiparae than in primiparae.

### 268. Pregnancy in Bicornuate Uterus

According to F. CLAUSSER (*Annals of Obstetrics and Gynecology* April 1927 p 157) pregnancy in a well developed and previous cornu of a bicornuate uterus usually continues to term the foetus being expelled naturally at term or less normal labour. Where the accessory cornu is rudimentary and atrophic about one half of the cases terminate in rupture with intraperitoneal haemorrhage. Clinically this is almost indistinguishable from ruptured tubal pregnancy but the rupture (owing to the more ample musculature in the accessory cornu than in the tube and to the pressure in the former situation of a decidua) occurs late usually during the fourth or fifth month of pregnancy. According to F. Hatch the mortality of rupture of a gravid horn in bicornuate uterus is over 50 per cent. If an operation is not performed soon after the rupture the usual sequel which may be late is suppuration or putrefaction of foetal remnants in the haematocele. Some, however, unmodified remarks are found later, or as in a personal case operated on nine months after rupture formation of a lithopædion occurs. In cases in which the cornu does not rupture the foetus dies a few days before term and undergoes auto-lolysis or mummification, or is transformed into a lithopædion.

## 269 Possibility of a Congenital Factor in Ectopic Pregnancy

W L CROWTHER (*Med Journ Australia*, April 23rd, 1927, p 610) reports three cases of ectopic pregnancy occurring in three sisters, and suggests that such an occurrence indicates the possibility of some congenital or familial cause being present. The first patient, aged 23, had given birth to a child two years previously. At the operation for the ectopic pregnancy a rupture of the left Fallopian tube was found at the junction of the middle and outer thirds. Inquiry in this case elicited the fact that the patient's two elder sisters, aged 35 and 41, had each required operative treatment for ruptured ectopic gestation on the right side. Crowther states that the mother of the three women concerned had given birth to eight children without any suggestion of such an occurrence in herself. The three patients were well above the average in general physique and health, and there was no evidence of any disease, the Fallopian tubes did not appear to be infantile, and no diverticula or accessory tubes were found.

## 270 Post-menopausal Bleeding and Cancer of the Ovary

C TILCONI (*Ann di Ostet e Ginecol*, June, 1927, p 381) states that in metrorrhagia after the menopause the practitioner should not content himself with searching for a malignant neoplasm of the cervix or corpus uteri (the most common causes), but should make a careful investigation also of the state of the adnexa. In a series of sixty cases of carcinoma of the ovary in patients who had passed the menopause Tilconi found that one third suffered from irregular bleeding, and in one fifth metrorrhagia was the earliest or a very early symptom. Vaginal bleeding occurred in the same proportion of cases in both solid and cystic carcinoma. Tilconi's conclusions confirm those of Schiffman, who in a brief period of time noted five cases of cancer of the ovary characterized by reappearance of hemorrhage after the menopause. The etiology of the uterine bleeding in cases of cancer of the ovary is uncertain, no menstrual changes were found by histological examination of the endometrium, and hormonal influences, as well as hyperemia, may be supposed to play a part in the neighborhood of the neoplasm.

## Pathology.

## 271 Systematic Immunization against Tetanus

G RAMON and C ZOELLER (*Ann de l'Inst Pasteur*, August, 1927, p 803) have performed a number of experiments on the immunization of human beings with tetanus antitoxin. The antitoxin is prepared from a freshly filtered tetanus toxin, about 2 c cm of formal is added per litre of toxin, and the mixture is incubated at 38° C for a month or so. The resultant product—the antitoxin—is highly antigenic, but quite non-toxic, it is, moreover, resistant to heat at 55° C. The antigenic value can be titrated by the Ramon flocculation test. Before commencing their vaccination experiments, the authors examined about 100 persons, mostly adults, for evidence of natural immunity to tetanus. This was done by mixing 1 c cm of the patient's serum with increasing doses of toxin, and injecting the mixtures into guinea pigs. In not a single person was there any antitoxin detectable. The effect of subcutaneous injections of antitoxin was then tried. They found that if 1 c cm of antitoxin was injected, the serum a month later contained only a trace of antitoxin. If a second dose of antitoxin was given a fortnight after the first, and the serum was tested a week later, it contained from 1 to 10 units of antitoxin. If the interval between the two doses was increased to three weeks, the titre of the serum rose to 10 to 20 units, and if the interval was increased to four weeks the titre rose to 100 units. A third injection of antitoxin given a week after the second raised the titre to 1,000 to 2,000 antitoxic units. When a person has been sensitized by a first dose of antitoxin he will respond rapidly to any subsequent injection. Having shown that it was possible to excite an active immunity by the injection of antitoxin, the authors investigated the possibility of producing a combined active and passive immunity. They found this was possible by the following method. At the first injection 10 c cm of antitoxin and 1 c cm of toxin are given—by separate routes, ten days later a second injection of 10 c cm of antitoxin is given, ten days later a second dose of 2 c cm of antitoxin is given. The antitoxin confers a passive immunity lasting for about three weeks, by which time the active immunity caused by the antitoxin has developed. In practice the authors recommend systematic immunization with three doses of antitoxin of all those who run a risk of contracting tetanus in their work, such as

grooms, farriers, and the cavalry, they think that this method should likewise be used in the army during wartime, a combined injection of tetanus antitoxin and T A B vaccine being given. The second method of antitoxin and antitoxin injections should be used for those who have suffered an injury likely to be followed by tetanus, in cases in which recovery is slow it obviates the necessity of repeated prophylactic injections of serum.

## 272 Pathology of Diphtherial Paralysis

M CINCULISCU and R HIRSCH (*Bull et Mem Soc Med des Hop de Bucarest*, March, 1927, p 39), as the result of the study of a case of diphtherial paralysis, come to the following conclusions: (1) The diphtheria toxin may be propagated from the primary focus in the throat to the nerve centres like tetanus toxin. This explains why the bulbar centres, for which diphtheria toxin has a special affinity, are chiefly affected, the affection of these centres being accompanied by a meningeal reaction of an inflammatory type with increase in the amount of albumin, cells, and fibrinogen, separately or combined. (2) The cardiac symptoms which may occur early or late are due to a lesion of the bulbar nuclei of the vagus or more rarely of the myocardium. The hypovagotonia produced may amount to complete paralysis, the clinical signs of which are obvious and the various biological and pharmacodynamic methods such as injection of atropine or pilocarpine are only required for studying their evolution. (3) It is probable, as the authors' case shows, that the nuclei of the sympathetic are affected as well as those of the vagus, but the symptoms of sympathetic involvement are latent and require a special investigation for their detection. (4) The persistence of the intoxication of the bulbar nuclei, even after the Schick and Zoeller test have become negative, indicates that serum treatment should be continued for a long time after the membrane has disappeared from the throat. It is not, however, necessary to give a large dose at one time, and small doses extending over a longer period are preferable.

## 273 The Bactericidal Activity of Hexylresorcinol in Glycerin

V LEONARD and W A FEIRER (*Bull Johns Hopkins Hosp*, July, 1927, p 21) state that four physical factors (concentration, temperature, pressure, and time) influence chemical disinfection. Billiard and Dieulafe have shown that by lowering the surface tension both osmosis and diffusion are accelerated. Hexylresorcinol, with a phenol coefficient of 72, is a most powerful germicide, and is practically as powerful in reducing surface tension as chemically pure sodium oleate. Owing to its relative lack of toxicity its use as an internal antiseptic has been investigated, but not its value as a general antiseptic for surface tissue disinfection. The present authors have made a number of experiments with a series of solutions (1 in 50 to 1 in 1000) of hexylresorcinol in various concentrations of glycerin and water. Although only slightly soluble in water, 1 mg of this salt reduces the surface tension of the fluid eight times as powerfully as the same concentration in pure glycerin, in which it is readily soluble. The addition of water to glycerin raises the surface tension, but if hexylresorcinol is present in the glycerin the addition of water reduces the surface tension and enhances the bactericidal action of the solution. As a result of these experiments Leonard and Feirer come to the following conclusions: (1) Surface forces play a major part in chemical disinfection. (2) Under equivalent conditions a germicide which depresses the surface tension of water is more efficient than one that does not, because, owing to the greater extensibility of the fluid film of low surface tension, the germicidal solution is more liable to penetrate minute inequalities in the surface, inaccessible to fluids of high surface tension. Moreover, germicides which reduce surface tension are adsorbed by particles in suspension, such as bacteria, and concentrate at the most effective point—namely, on the surface of the organism—while diffusion of the germicide through the cell membrane of the organism is accelerated as the surface tension is lowered. (3) The bactericidal activity of hexylresorcinol in solutions of glycerin and water is inversely proportional to the surface tension of those solutions, the lower the surface tension the greater is their bactericidal activity. (4) A solution containing 30 per cent glycerin and 70 per cent water, in which is dissolved 1 mg of hexylresorcinol per c cm (1 in 1000), appears to represent the optimum composition for clinical application in tissue surface disinfection, since it is non-toxic and non-irritant. The salt is held in perfect solution in all dilutions, the surface tension is very low, all the major pathogenic microorganisms are destroyed in less than fifteen seconds, and its bactericidal activity is retained under all conditions of dilution likely to be encountered in clinical application as well as in the presence of organic matter.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine

### 274. Metacetaldehyde Poisoning

W H WILLCOX and O AINSWORTH MITCHELL (*Analyst*, September, 1927, p 523) report a case of metacetaldehyde poisoning in a boy, aged 16, who swallowed about 5 grams of a double tablet of the solidified fuel used as a substitute for methylated spirit. About seven hours later the patient became flushed, restless, and delirious, the temperature rose to 100° F, and convulsions occurred at intervals during the following fourteen hours. The boy was semi-comatose in the intervals between the convulsions. The urine was very acid and contained a trace of albumin, there was marked tenderness of the calves of the legs. The temperature remained between 100° and 101° for thirty six hours and then fell to 99°, at which point it persisted for twenty four hours after which it became normal. Large doses of all salts in the form of sodium citrate 60 grains, sodium bicarbonate 30 grains, water 1 oz were given every four hours, by the mouth, and rectal injections of normal saline solution containing sodium bicarbonate were administered every six hours. Chlorid and potassium bromide were given during the convulsion period. The urine remained very acid for three days in spite of large doses of alkali. After the convulsions had ceased potassium bromide in 15 grain doses was given three times a day for four days. The patient made a good recovery, but the albuminuria persisted for four days and there was some loss of memory at first. Examination of the solidified fuel showed that it agreed in its reactions with metacetaldehyde and the authors comment on the fact that this substance should be so much more active than its isomer paraldehyde. It is however, possible that traces of the condensation agent used in its preparation may have been left in the final product. A warning is given that this fuel ought not to be left within reach of children.

### 275. Myositis Ossificans Progressiva

A R KOOTZ (*Amer Journ Med Sci* September 1927 p 400) defines this condition as characterized by multiple if not generalized, ossification of the voluntary muscles without apparent cause, and by a progressive course with periodic exacerbations. Frequently a slight injury is associated with the initial ossification. The disease is congenital or appears early in life, and most cases show an anatomical anomaly of the great toes or thumbs as microdactylia or brachydactylia. There have been reported 133 cases of this disease and the author describes a further case in a girl aged 17½ the disease started when she was 9. Beyond the marked ossification of numerous muscles and ligaments the absence of axillary and pectoral hairs and the maldevelopment of the breasts the patient showed no objective symptoms the thoracic and abdominal organs being normal and the renal basal metabolism and blood calcium and phosphorus falling within normal limits. The age incidence of this malady is noteworthy of 116 cases in which the age of onset is stated 79 occurred during the first five years of life and only one after the twentieth year. Of 126 cases in which the patients sex is stated 75 were males and 51 females. The commonest site of origin is in the cervical and dorsal regions the disease then spreading to the upper and lower extremities. The onset is characterized by fever, and a pasty swelling and redness of the affected part, which gradually hardens as bone is formed. These swellings are sometimes painful owing to spontaneous haemorrhage in the muscles. Defective development of the sexual organs or functions sometimes occurs. Only one case has been reported in which bone has formed in the skin as well as the muscles. Many pathological studies have been made and in one case De Witt reports a microscopic picture of degenerating muscle and leucocytic infiltration with granulation tissue replacing the larger inflammatory areas. In the new granulation tissue, and only in it irregularly branching and anastomosing trabeculae of osteoid tissue are always found. Many theories have been advanced as to the cause of myositis ossificans but none have been proved experimentally. Lewis has suggested that the cause may be an excessive production of sarcolactic acid in the muscles. Diagnosis is easy though the circumscribed form frequently has to be distinguished from sarcoma. The differential points are that sarcoma occurs more often near the epiphyses myositis ossificans along the diaphyses the growth of sarcoma is steadily progressive rather than spasmodic and the tumour never becomes smaller as it frequently does late in myositis ossificans. Sarcoma also gives a more

distinct x-ray picture. The disease progresses steadily but periodically over a number of years. Normal activities, not much affected at first, become more and more curtailed, and death may finally occur from starvation due to ossification of the jaw muscles. Numerous drugs have been used in treatment but without success. Roentgen rays have been tried, but these seem to stimulate rather than retard the disease. Lublich recently advocated a ketogenic diet, and gave his patient food poor in carbohydrates and rich in fats for one and a half years. Acetone bodies were always present in the urine. No more calcareous areas developed, and of these already present some disappeared and others diminished greatly in size.

### 276. Tuberculosis in Java

J L SUTER (*Nederl Tijdschr v Geneesk*, August 13th, 1927, p 726) records his observations on the morbid anatomy of tuberculosis in Java in a paper based on the study of 3155 patients who had died from the disease between September 1913 and December, 1926. As a rule tuberculosis assumed the form of a chronic pulmonary disease but with a much more rapid course than in Europe. The lymphatic glands were affected in most cases, their involvement being apparently secondary to the lung condition. Intestinal tuberculosis was a frequent occurrence in the last stage, and was rarely seen as a primary phenomenon. The larynx was also often affected terminally and primary laryngeal tuberculosis was not seen. Tuberculosis was often found in the spleen, frequently in the form of milary tubercles, and occasionally as numerous large caseous foci, tubercles were frequently found in the liver but extensive lesions were rare. The urogenital system was only rarely affected apart from a few tubercles in the kidneys in the last stage. Tuberculosis of the brain was rare. The heart and endocrine organs were occasionally attacked. It was very unusual to find well marked involvement of the serous membranes. Although the bones and joints were frequently attacked the long bones often escaped. The skin was occasionally affected. Acute generalized tuberculosis was rare. Occasionally the pulmonary disease was masked by process in the serous membranes or lymphatic glands, or on the other hand, the lungs played the most prominent part in the clinical picture by the development of tuberculous pneumonia. In such cases it was not impossible that the acute course was connected with unfavourable external circumstances.

### 277. Serum Prophylaxis of Measles.

R TUNNICLIFF and B WHITE (*Boston Med and Surg Journ*, August 18th, 1927 p 272) immunized a horse by subcutaneous injection of broth cultures of the green producing diplococcus which Tunncliffe regards as the causal agent of measles and when a basal immunity was established injected living diplococci according to the method described by Dochez for producing scarlet fever antitoxic serum. The serum was concentrated and when tested in both concentrated and unconcentrated states was found to contain opsonins and to produce neutralizing and protective effects specific for this diplococcus. Injection of children previously exposed to infection with this serum apparently gave complete protection in a few cases incomplete protection in some, and no protection in others. Further clinical tests are being made with the concentrated serum.

### 278. Bacteraemia in Diphtheria

E MARTNER (*Amer Journ Dis Child* June 1927 p 895) reviews the literature and records his own observations on blood cultures in diphtheria in 40 cases. The patients selected were those who had not had any antitoxin before admission. He withdrew 10 c cm of blood from the elbow veins—in young children from the jugular vein—and placed it immediately in 1 per cent glucose broth. The flasks were incubated for at least twelve hours before examination and if sterile were re-inoculated and examined at the end of twenty four, forty eight and seventy two hours. In cultures presenting growth subcultures were made on Loeffler's blood serum and blood agar plates. Of the forty cases six showed a blood stream infection—namely pure cultures of *B. diphtheriae* in three and a haemolytic streptococcus in three. The cultures were all positive at the end of the first twenty four hour period of incubation. Two of the cases of *B. diphtheriae* infection were true haemorrhagic diphtheria, and the third showed haemorrhages from the nose and mouth before death. The patients with streptococcus infection had the septic type of diphtheria.

## 229 Incidence of Varicella

A G MITCHELL and E G FLETCHER (*Journal Amer Med Assoc*, July 23rd, 1927, p 279) record the data relating to the age seasonal incidence, recurrences, complications, and leucocyte counts in varicella in a paper based on the statistical study of 775 cases admitted to the contagious diseases department of the Cincinnati General Hospital from 1913 to 1926. The writers remark that the number of adults who contract the disease is not sufficiently appreciated. Of the 775 cases 150, or 19.4 per cent, were above 10 years of age, 118 being between 20 and 30, 26 between 30 and 40, and 6 over 40, the oldest being 55. Many of the patients were sent to hospital with a diagnosis of variola, and a few were physicians, nurses, and attendants, who contracted the disease in hospital. The greatest number of cases occurred in the winter months, there being 67 per cent in the six-month period November to April. Only nine patients, aged from 2 to 21, gave a history of a previous attack. Complications were rare and nearly always mild, the commonest being furunculosis and otitis. Only two deaths occurred, one from streptococcus meningitis following furunculosis, the other a child who contracted varicella while suffering from tuberculous broncho-pneumonia. The average leucocyte count was 3,000 per c mm above normal in infants. There was a slight leucocytosis, especially in infants, but no important change in the differential count.

## 230 Nervous Complications of Varicella

M PRUVOST (*These de Paris*, 1927, No 62), who records an illustrative case with a review of the literature, remarks that varicella may be followed by nervous manifestations similar to those complicating other infectious diseases. The virus or toxin of varicella may affect all the segments of the cerebro-spinal axis, so that cases are on record of peripheral neuritis, such as that reported by W GAY (*JOURNAL*, March 31st, 1894, p 673), myelitis, meningitis, acute cerebellar ataxia, and encephalitis. It is not necessary that the attack of varicella should have been remarkably severe to produce these sequelae. Pruvost's patient was a boy, aged 4, who four days after the onset of an ordinary attack of varicella developed symptoms of meningitis (nuchal rigidity, Kernig's sign, and cerebrospinal hypertension) and encephalitis (irritability followed by somnolence). Complete recovery followed.

## 231 Hypotension

ACCORDING TO A FRIEDLANDER (*Medicine*, May, 1927, p 143), though low blood pressure is a symptom or manifestation of an abnormal bodily state rather than a disease itself, in many persons it is certainly compatible with perfect health. In the newborn and in childhood hypotension is a physiological condition, adult levels not being reached until the age of 18. As a morbid phenomenon it may be temporary or persistent. Acute hypotension is a feature of traumatic, anaphylactic, and anaesthetic shock. It occurs in acute infectious diseases, notably typhoid fever and diphtheria, and it may be the result of certain drug intoxications. Persistent hypotension is associated with certain chronic infectious diseases, especially advanced tuberculosis and cachectic states. It is found in such diatheses as infantilism, status lymphaticus, myxoedema, and myasthenia. Lesions of the circulatory system, particularly of the myocardium, may produce either temporary or persistent hypotension. Essential hypotension forms a fairly definite clinical syndrome, the nature of which is still unexplained. Chronic hypotension occurs in endocrine dysfunction, especially of the adrenals, hypophysis, gonads, and thyroid gland. The author adds that progress in the treatment of hypotension must await the carefully planned and united efforts of physiologists, chemists, pharmacologists, pathologists, and clinicians.

## 232 Epidemic Encephalitis in Japan

M TSURUMI (*Bull Office Internat d'Hyg Publ*, June, 1927, p 799) states that epidemic encephalitis appeared in Japan in August, 1924, and rapidly spread through the country, so that by the end of September there had been 6,547 cases, with a mortality of 54.9 per cent. The great majority of the patients were elderly, more than 80 per cent being from 50 to 70 years old. The sexes were equally affected. After a stage of slight fever, headache, pain in the trunk and limbs, and vomiting lasting for a few days, the temperature rose suddenly to 105° and spasmodic movements developed in the extremities, there was loss of consciousness or, in the milder cases, profound somnolence. No disturbance of vision was noted, as is the rule in lethargic encephalitis. In the cases which recovered there were usually no serious sequelae apart from rigidity of the arms and legs. In fatal cases death, as a rule, occurred five to ten days after the onset, sometimes on the very first day. No causal organism was discovered. Necropsies confirmed the diagnosis of encephalitis.

## Surgery.

## 233 Post-Influenzal Pseudo peritonitis

F FRANK (*Zentralbl f Chir*, August 6th, 1927, p 202) comments on W Usadel's report of appendix symptom appearing in a diabetic patient (see *Epitome*, August 13th, 1927, para 114) and agrees that neuralgias of the spinal nerves, such as sciatika and herpes zoster, occur more frequently in diabetics. Frank states also that crises of neuralgia of the spinal, and particularly of the intercostal, nerves have been much more common since the great influenza epidemic of 1889-90, and many more cases followed the pandemic of 1918-19. He insists that the possibility of influenzal neuritis must always be borne in mind, not only in thoracic diseases such as pleurisy, early pneumonia, and heart disease, but also by surgeons and gynaecologists in the presence of symptoms of serious abdominal disease, such as gastric ulcer, biliary colic, appendicitis, peritonitis, and oophoritis, whether febrile or afebrile. The importance of correct diagnosis in such cases is very great, as a large number of diagnostic errors and unnecessary operations have been recorded. Frank reports the case of a man, aged about 40, who was sent to hospital for operation for perforation peritonitis. The patient was febrile, with a haggard expression, tenderness on pressure over the upper abdomen, and muscular rigidity, there was no evidence of free gas in the epigastric region. The pulse was severely accelerated. The patient had had influenza a week earlier. There was hyperaesthesia of the abdominal skin, and the corresponding intercostal nerve were very painful on pressure. Frank diagnosed intercostal neuritis, and prescribed phenacetin, this gave speedy relief. However, the next day symptoms of peritonitis were more definite, but as the patient had been relieved previously by phenacetin the dose was repeated. In twenty minutes the patient was free from pain and his condition improved. Fever persisted for two days, then the pain and all signs of abdominal disease disappeared, and the patient made a rapid recovery.

## 234 Late Results of Operations for Gall Stones

ACCORDING TO E DAHL IVERSEN (*Acta Chir Scand*, August 25th, 1927, p 235) up to the year 1910 cholecystostomy was the most favoured operation for gall stones, since when most surgeons have shown a preference for cholecystectomy. The literature of the subject consulted by the author indicates that the operation mortality is the same for the two methods. True relapses are rare after both, but false or pseudo relapses caused by overlooked calculi, inflammation, or adhesions are a little more frequent after cystostomy. To throw further light on this matter the author has re-examined 196 patients who were operated on by P N Hansen between 1913 and 1925 at the fifth surgical service of the Kommunalt Hospital in Copenhagen. The number of patients undergoing cholecystectomy was 156, and the number treated by cholecystostomy was 40. Only in one case was a true relapse recorded. The patient was a woman, aged 32, who had suffered from several attacks of colic with fever and jaundice between 1915 and 1920. The removal of two calculi at the first operation, which showed free biliary passages, was followed by renewed attacks of colic, fever, and jaundice. The removal of another calculus at a later operation gave freedom from similar attacks. In 75 cases the after examination was made twice, the first occasion being one year after the operation and the second several years later. In these cases it was noticed that most of the patients who were well a year after the operation continued so for many years. The incidence of true and pseudo relapses was the same (19 per cent) for the two kinds of operation. With regard to the pseudo relapses, it was impossible to distinguish between the principal causes thereof—namely, overlooked calculi, inflammation, and adhesions. The author concludes that the available evidence does not justify giving preference to cholecystectomy at the expense of cholecystostomy, and he suggests that the re-examination of a larger number of patients operated on according to one or other of these methods should show which is the better.

## 235 Diverticula of the Duodenum

J W LIVINGE and E A GILHAM (*Surg, Gynecol and Obstet*, September, 1927, p 257) report operations upon three cases of diverticula of the duodenum, and discuss the importance of cholecystitis in the production of symptoms. One patient had a large false diverticulum and two had pseudo-diverticula or redundant duplications of the duodenum within its retroperitoneal sheath. In these the gall bladder was diseased, and cholecystectomy relieved all symptoms, though the duplicature or practical diverticular side pockets of the duodenum persisted. A very demonstration of their presence depends upon the appearance of an

abnormal side pocket, which fills and empties from the duodenum; the majority are on the superior and descending portions and lie within the loop of the duodenum. A gall stone picture may simulate a diverticulum if it is forced out in connection with the barium meal but this possibility can be eliminated by an independent examination. Because of the importance of the gall bladder in clinical symptoms with which duodenal diverticula may be associated cholecystography is advocated as an essential procedure in diagnosis.

### 256. Cervical Dislocation

V. F. MARSHALL and C. C. HALL (*Ann. Surg. Med. Sci.*, July 16th, 1927, p. 191) report a case of displacement forward and to the right of the atlas and axis on the third cervical vertebra with distinct anterior posterior angulation between the third and the second and first cervical vertebrae as the result of a fall from a motor car. Under nitrous oxide oxygen anesthesia the dislocation was reduced by Wilton's method, and a light plaster cast was applied to the shoulders, neck, and head. The condition recurred next day and after reduction a plaster collar was put round the neck over which a fairly heavy cast including the shoulders, neck, and head was applied. Five months later there was no deformity or limitation of movement. In complete unilateral dislocation the articular process of one vertebra slips forward into the intervertebral notch of the one below. In Wilton's method of reduction the depressed process is raised and rotated by extending the head obliquely backward toward the right or left as the case may be using the transverse process on the same side as a fulcrum. Force is not needed thus to elevate and rotate into proper position since the ligaments offer no opposition to the movement. The patient should be thoroughly anesthetized in the sitting position to permit freedom of movement and to prevent any restriction of the procedure of reduction.

### 257. Osteitis Fibrosa.

W. DEGA and J. ZFYLAND (*Lyon Chir.* July-August, 1927, p. 377) remark that the pathology of osteitis fibrosa is still somewhat obscure. Many theories have been advanced to account for the condition but none appear sufficiently convincing up to the present. It is suggested now that osteitis fibrosa is not a disease in itself but is rather a reaction to some affection of the lung tissues. This condition has been found around malignant tumours and near long standing osteomyelitis. The authors report a case where osteitis fibrosa was found in the head of the first metatarsal bone in a case of hallux valgus. Examination of the bone showed there was a marked sclerosis of the blood vessels, possibly the result of repeated small injuries this appeared to induce pathological sequelae similar to those seen in osteitis fibrosa. The changes in this case were purely local but other writers have reported cases where the condition was more general. While not wishing to speak too definitely the present authors think it not unlikely that the disease may be due to the effect of certain changes in the blood vessels, possibly quite localized, and not of a general specific character.

### 258. Multiple Suppurative Osteoperiostitis in Typhoid Fever

E. RIST, A. RAVINA, and B. WARTZ (*Bull. et Mem. Soc. Med. Hop. de Paris* August 4th 1927, p. 1285) record the case of a woman aged 23, who in the course of six months following an attack of typhoid fever presented suppurative osteitis of the tibial cranium humerus, rib and ilium. Unlike Emile Weil who had remarkable success in the treatment of typhoid osteoperiostitis with specific vaccines the authors found that this method had no beneficial effect but caused a local reaction at the site of injection and a sufficiently severe febrile reaction to necessitate discontinuing the treatment. Recovery ultimately occurred.

### 259. Gangrene in Epidemic Meningitis

S. LEVY (*Zeit. f. Kinderheilk.* August 17th 1927, p. 230) records the following case which he thinks must be unique. About a month after a severe attack of meningococcal meningitis in an infant aged 2 months asphyxia of both hands and feet developed. This subsided in the course of a day in the feet and left hand while in the right hand gangrene followed, causing loss of the terminal phalanx of the index finger and small necroses of the other fingers. Necrotic areas also formed simultaneously on the left parietal bone. No fresh necroses ensued in the course of fourteen months but death occurred after signs of increasing hydrocephalus. There was no necropsy. Although the clinical involvement was in favour of thrombosis or endarteritis, there was no evidence of cardiac disturbance and Levy is inclined to regard the case as one of Raynaud's disease.

### 290

### Otitis

G. COLLET (*Arch. Med. Nat.*, June 15th 1927, p. 314) draws attention to the prognostic gravity of those cases of acute otitis which are associated with severe neuralgia of the trigeminal nerve. He describes five cases in illustration of this. Of the three patients died of meningeal complications. He emphasizes the danger that is likely to arise when an acute otitis is accompanied by severe neuralgia in the distribution of the fifth nerve and suggests that the otitis serves as a starting point for an osteomyelitis of the petrous bone. He concludes that it is necessary to operate early in these cases.

## Therapeutics

### 291. Splenic Anaemia Treated by Fresh Calf Liver

N. FILSINGER and R. CASTERAN (*Bull. et Mem. Soc. Med. des Hop. de Paris* August 4th 1927, p. 1253) report the case of a woman aged 53 whose illness commenced in 1923 with general weakness, anaemia, digestive disturbance and later, jaundice. When first seen by the authors in February 1927 her spleen was palpable three fingerbreadths below the costal margin, there was marked anaemia and slight enlargement of the liver with jaundice. Her Wassermann reaction was negative. She was given 250 grams of fresh calf liver daily and a little later heavily intravenous injections of 0.10 gram of novarsenobenzol. Definite improvement was noted in six weeks, and a little later the injections were stopped, a total of 1.4 grams of novarsenobenzol having been administered. She continued to take 250 to 270 grams of fresh calf liver daily and in May was also given iron and arsenic. On July 1st she was reported cured, her spleen was not palpable, the blood picture was normal and the jaundice had disappeared three months previously. She had gained nearly 50 lb in weight and after having been confined to bed for many months was now able to take walks. The authors recommend that the calf liver should be made up in sandwiches with anchovy paste.

### 292. Cocaine Treatment of Ophthalmia Neonatorum

L. WEISS (*Journ. Med. Soc. N. J.* May 1927, p. 250) recommends the instillation of 4 per cent cocaine solution for the prophylaxis and treatment of ophthalmia neonatorum on the ground that it renders the conjunctiva anaemic and unsuitable for bacterial growth. He thinks that the present practice, which aims at destroying the bacteria *in situ* with silver preparations is of little value. As a prophylactic several drops should be instilled into the lower conjunctival sac immediately after birth and once daily during the following week the closed eyelids having been cleansed gently with sterile swabs without eversion of the lids. If ophthalmia commences the drops are instilled every two hours the pus being wiped away after the inflamed lids have been gently separated, no attempt is made to press it out. This treatment requires two attendants working in relays every few minutes for from twenty four to forty eight hours since the formation of pus is continuous as the inflammation begins to subside the frequency of instillation and swabbing is reduced. Weiss considers that cocaine solution by anesthetizing and blanching the conjunctiva increases its resistance to bacterial invasion and combined with gentleness in cleansing the lids to prevent complications he regards it as an ideal remedy in prophylaxis and treatment.

### 293

### The Treatment of Tinea Cruris

H. W. ACTON and C. MCGUIRE (*Indian Med. Gaz.*, August 1927, p. 419) assert that in tinea cruris an acute pyogenic infection is always secondary to ringworm and that the septic condition should be dealt with first, strong parasitocidal remedies can be used only after this infection has subsided and reinfection is very possible. Treatment is therefore divided into three stages. (1) In the acute stage only the mildest remedies can be used since a severe and an acute spreading dermatitis may be caused. In streptococcal infection the best application is calamine lotion to which a marked pruritus carbolic acid or aqua lanocera can be added. When impetigo is present unguentum hydrargyri ammoniacum dilutum should be used at night and the lotion during the day. In staphylococcal infections the pustules should be opened and acridine (1 in 1000) employed. In the stage of resolution the best treatment is calamine to ointment by day and Lasar's paste without salicylic acid at night. If the paste proves too strong an ointment containing zinc oxide and starch is advised. (2) When the acute symptoms have subsided the parasitocidal remedies may be used. Removal of fungal roots should be aided by a rapid surface desquamation effected by the judicious use of pumice stone.

thickening of the skin being prevented by protective applications. The best keratolytic agent is said to be Whitfield's ointment containing benzoic and salicylic acids, which, if irritant should be combined with calamine lotion. When there is great interdigital thickening resorcin, applied every night is the best remedy unless irritant, when a simple ointment should be used. Chrysotolin should never be employed when fissures or the slightest inflammation are present. For chronic cases dry treatment is advised. When secondary pyogenic infection exists care should be exercised in the length of exposure, and treatment stopped on the slightest signs of any reaction. Relapses respond readily to further irradiation. In nail infection, the nail should be removed, the bed scraped, and an ointment, such as Whitfield's, applied. (3) For the prevention of relapses the disease must be eradicated from the skin surface, the interdigital clefts and grooves, where the disease may lurk, being carefully examined. Infected clothing must be boiled and the toes cleansed by swabbing with pure lysol. Skin infection can easily be prevented by the use of a sulphur antiseptic powder, and, after bathing, likely areas of infection should be lightly dusted with a salicylic talcum powder. Friction and moisture play an important part in causing infection. Friction can be prevented by the use of properly fitting footwear and clothes, and moisture by dusting the parts with an absorbent powder and allowing free ventilation by the use of properly fitting clothes.

#### 274 Iodine in Primary Hyperthyroidism

H. M. CLURE and R. L. MASON (*Boston Med and Surg Journ*, August 18th, 1927, p. 247) discuss the use of iodine as a therapeutic aid to surgery in primary hyperthyroidism. They compared 100 selected cases in which a solution of iodine in hydrochloric acid was used with those in which Lugol's solution was administered, and conclude that the particular solution used is immaterial, the important point being the preoperative administration of an excess of iodine. The daily dose of Lugol's solution was 30 minims, and that of the hydrochloric acid iodine solution (1 c.c.m. containing 100 mg of iodine) was 60 minims. The basal metabolic rate was determined on alternate days before the operation and on the sixth day afterwards. An excess of iodine was found to be preferable to long standing continued small doses, and continuation of the iodine therapy for at least three months after operation is recommended. The improvement in subjective symptoms following iodine administration in preparation for operation was striking, restlessness rapidly disappeared and tremor decreased, with recession of the exophthalmos in a few cases. In about 12 per cent of the cases iodine had no apparent effect upon the symptoms. In the treatment of recurrent or persistent hyperthyroidism after thyroidectomy iodine is of value and in some cases will control the recurrence of toxic symptoms, but persistent elevation of the metabolic rate indicates that too large a remnant of active thyroid tissue has been left and that a further operation is needed to remove more of the gland. The authors state that iodine alone will not cure, and an operation should, therefore, be performed at the time of maximum improvement following its administration. Although the treatment is contraindicated in patients who have large single adenomatous goitres with secondary hyperthyroidism, it is suggested that it may be cautiously tried in preoperative preparation for multiple adenomatous goitres with hyperthyroidism.

#### 295 Digitals in Pneumonia

W. S. BURRAGE and P. D. WHITE (*Amer Journ Med Sci*, August 1927, p. 260) comment on the differences of opinion as to the efficacy of digitals in pneumonia. Mackenzie, Hume, Branton, and White, among others, consider that its administration is useless, if not harmful, while Cohn and Jamieson, Brooks and Carroll, Phillips, Bliss, and Stone, hold the contrary opinion. In the hope of obtaining further data the present authors studied a series of 221 cases of lobar pneumonia treated in the Massachusetts General Hospital from January, 1921, to December 1925. A study was made of the type of pneumonia in all the cases, and of complications serious enough to influence prognosis apart from the original pneumonic process. In this group of patients, all of whom were adults, approximately one half received digitals in varying amounts, the other half none at all. The former showed a mortality two and a half times that of the latter. The patients receiving digitals were divided into those who were digitalized and those who were not. Digitalization was computed upon the basis of  $1\frac{1}{2}$  grains for every 10 pounds of body weight, the average dose being 36.5 grains per patient, administered in large part in  $1\frac{1}{2}$  grain pills in the course of two, three, or four days. In the undigitalized group, the drug was administered unsystematically in many instances, being used as a last resort in about one half of the cases when they were very seriously ill. The digitalized patients showed a mortality only five eighths as high as those who

were given no digitals whatever, while those treated by non digitalizing doses showed a mortality three and a half times as high as those who received no digitals. In this series of cases, in which the percentages of complications and dangerous patients are very similar, the lowest mortality rate was found in digitalized patients, and the next in those who received no digitals. The authors think that the definitely higher mortality among non digitalized cases should discourage this type of administration, if the drug is used, full digitalization should be ensured. It appears that systematic administration of digitals in such full doses may have been of benefit, and no untoward toxic effects were observed. While acknowledging that a larger series of cases must be carefully studied before conclusive evidence can be obtained, the authors believe that the data from the present series suggest that digitals is of value in pneumonia when given in sufficiently large doses.

#### 296 Metallic Salts in the Treatment of Infections

L. E. WALBUM (*Ugeskrift for Læger*, July 14th, 21st, and 28th, 1927, pp. 612, 644, and 671) gives a detailed account of experiments on mice, rabbits, and guinea pigs infected with tetanus spores or tubercle bacilli, and treated with small doses of the salts of various metals, such as manganese, cadmium, and cerium. After inoculating mice with virulent tetanus spores and subsequently with a culture of staphylococci he was able, to eradicate these organisms completely by a series of subcutaneous injections of small (optimal) doses of manganese. He publishes a table showing the fates of these mice and of the controls. The tetanus spores in the bodies of the mice lost their virulence some time before they were destroyed. Rabbits infected by the intravenous route with virulent tubercle bacilli were protected from contracting tuberculosis when they were treated, within seven days of the infection, with small doses of manganese, cerium, lanthanum, or cadmium. The tubercle bacilli were either destroyed or lost their virulence, the same observations being made in this respect as those made by Madsen and Moich in their experiments with snocysin. Rabbits already tuberculous were cured by small doses of cadmium, provided it was given within thirty-three days of their intravenous infection with virulent tubercle bacilli, but in no case did small doses of cadmium protect guinea pigs against the subcutaneous injection of virulent tubercle bacilli, though mice infected with these were completely cured by small doses of manganese. The author suggests that Ehrlich's success, with large doses of salts in the treatment of protozoal infections has misled research workers, who have sought to overcome bacterial diseases by massive doses on the assumption that they act directly on the invading microbe. The author ascribes the successes he has achieved to the indirect action of the injected salts, which, he assumes, stimulated the body to defend itself.

#### 297 Treatment of Diabetes

H. SCHWAB (*Paris méd*, August 13th, 1927, p. 135) states that O. von Noorden of Frankfurt has recently published the results obtained by treatment of diabetes with fermented and desiccated powdered pancreas, to which has been given the name of glucorment. It is best suited for mild and moderate cases of diabetes, in which 25 units and more of insulin can be replaced by glucorment. In severe cases two or three injections of insulin may be reduced to only one by its use. Von Noorden, who has treated a hundred cases of diabetes of different degrees of severity, states that one tablet of glucorment should be taken after each of the three meals. If five tablets are required the fourth and fifth should be given at 10 a.m. and 4 p.m. respectively. In eight to ten days the number can be reduced from five to three. The diet should consist of large quantities of protein, little fat, and 100 to 120 grams of bread. The reduction in the glycosuria is noted after the fifth day. The blood sugar diminishes without being affected by the meals. Hypoglycaemia has not been observed. The chemical composition of glucorment has not yet been discovered, but German writers maintain that it is chiefly composed of amides and does not belong to the guanidine group. Von Noorden, whose hypothesis is supported by Schwab, suggests that the substance is already present in the organism and that it is the capacity of reinforcing the action of insulin.

#### 298 Malariotherapy of General Paralysis

A. MARIE and F. M. A. LEGENDRE (*Bull Soc de Med*, June 8th, 1927, p. 200) maintain that the psychiatrist needs the help of the biologist in treating general paralysis by the inoculation of malaria. Most psychiatrists are agreed that ten febrile attacks are sufficient, after which it is desirable to bring about cessation of the fever and disappearance of the malarial parasites from the blood. In benign tertian fever caused by *Plasmodium vivax* the schizonts and gametes disappear after the ingestion of 1 gram of quinine hydrochloride, sulphate, or

stovarsolite for three days, or six to ten tablets of stovarol in doses of two daily. *Stovarsolite malitiae*, the parasite of malarial fever, is usually more resistant, so that it will be necessary to give quinine hydrochloride or sulphate in doses of 1 gram daily for ten days. Stovarsol alone can not cause the *Stovarsolite malitiae* to disappear, but is useful as an adjunct. The ring forms of *Stovarsolite malitiae*, the causal agent of malarial fever, disappear in four days with a daily dose of 1 gram of quinine hydrochloride or sulphate, but a treatment of almost a month is required to cause disappearance of the crescent. The authors add that although injections of quinine should be avoided, owing to the caustic action of the alkaloid, a pernicious attack of malarial infection should be cut short by an intravenous injection, given very slowly, of 0.8 gram basic form of quinine diluted in 20 to 100 c.c. of normal saline solution.

## Ophthalmology.

### Tumours of the Optic Chiasma

CHRISTIANSEN (*Praxelles Med.*, July 31st 1927, p. 1246) discusses the diagnosis of tumours in the region of the chiasma and sella turcica. Among the earliest symptoms is impairment of vision sometimes purely subjective of one eye only, inconstant, and not accompanied by any obvious changes in the fundus detectable by the ophthalmoscope. In other cases there are all grades from this up to complete blindness affecting both eyes, often very rapid in development, and associated with a diminished visual field and varying degrees of papillary atrophy. In the less advanced cases Christiansen urges the necessity for examination with colours, simple achromatopsia of more or less severity is sometimes the only symptom. He has not gained much assistance from x-ray examination because the pictures obtained are difficult to interpret and are frequently misleading, owing to the varying configuration of the sella turcica and ethmoidal and sphenoidal spaces in healthy subjects but he considers that definite increase in the depth of the posterior portion of the sella turcica, and especially of the posterior clinoid processes, are of local diagnostic value, the determination of calcification of the tumour being the most convincing sign. Examination of the cerebrospinal fluid in many cases reveals a very large number of cells up to 21,000 per cubic millimetre (pleocytosis), the cells being chiefly lymphocytes, which are usually accompanied by polymorphs and large mononuclear. The fluid is always sterile and contains no micro-organisms. There are no signs clinically of cerebrospinal meningitis, even in those cases with extreme leucocytosis.

### Optic Neuritis Following Whooping cough

G. H. HOGG (*Med. Journ. of Australia*, June 4th 1927, p. 825) records the case of a boy aged 16 who developed double optic neuritis in the earliest stage of pertussis before the whoop was heard. There was no meningitis or brain compression nor could mechanical factors be advanced as an explanation. The neuritis was apparently due to the toxins of the disease. Complete recovery occurred within three months. Hogg has collected six other cases recorded by Callan (1839), Alexander (1888), Jacobi (1891), Gamble (1905), Wiegmann (1912) and Nacht (quoted by Wiegmann) respectively, in patients aged from 6 to 40. Two of these became affected by optic neuritis two to four weeks after the appearance of whooping cough, two after several weeks and one after some months while in the sixth patient brain trouble occurred in the third month and was followed later by optic neuritis.

### Autohaemotherapy in Ophthalmology

MALLOL DE LA RIVA (*La Med. Ibera*, August 6th 1927, p. 109), who records an illustrative case states that autohaemotherapy in ophthalmology was first introduced by Rohmer of Nancy in 1911, who reported a case of corneal abscess complicated by hypopyon successfully treated by this method. Subsequently his son A. Rohmer published a thesis on the results obtained by autohaemotherapy in various ocular affections. Later Dauter recommended its employment in haemorrhages in the vitreous but it was not until March 1922 when Schachman recorded the brilliant results obtained by subcutaneous injection of 1 c.c. of the patient's debrided and centrifuged blood in five cases of ophthalmia neonatorum and one of gonorrhoeal conjunctivitis in an adult that the method became generally adopted. G. Busch (1926) has used the method with success in particular affections of the eye such as keratitis with hypopyon and severe purulent destruction of the cornea. The present author's case was that of idiopathic iritis in a man, aged 25, in whom the usual treatment failed but rapid recovery followed three intravitreal injections of 3 to 5 c.c. of the patient's blood.

### Parinaud's Conjunctivitis

A. GIFFORD (*Amer. Journ. of Ophthalmol.*, July, 1927, p. 481) describes three cases of this condition, in all of which the differential blood count revealed an eosinophilia and an increase in large mononuclears. Two of the cases were seen in a very early stage, the initial lesion being a small polyoid nodule situated in the lower fornical fold. Subsequently the usual picture appeared of numerous enlarged follicles showing points of necrosis, with a few granulations and with glandular involvement. Gifford thinks a likely mode of infection is from infected foreign bodies becoming embedded in the conjunctiva. He does not believe that the infection is necessarily always of animal origin. Two cases showed a Gram positive thread like organism corresponding with the leptothrix described by Verhoeff as being always found in these cases.

### Excessive Divergence.

J. H. DUNNINGTON (*Arch. of Ophthalmol.*, July, 1927, p. 344) is convinced that the act of divergence is active and not passive. He describes the condition of divergence excess, which may not give rise to symptoms though they usually supervene sooner or later, and include a feeling of strain on looking at distant objects—the so-called panoramic asthenopia—and at moving objects. A later sequel is a convergence insufficiency developing in association with divergence excess which must be distinguished from (1) convergence insufficiency and (2) insufficiency of an adduction. In the first of these two the distant readings are normal, while divergence excess gives normal near findings. When an adductor muscle is concerned there will be definite impairment of movement inward of the affected eye. The treatment is surgical and Dunnington advises complete tenotomy of the external rectus of one or both eyes.

## Obstetrics and Gynaecology

### Cautery Amputation of Cervix

H. P. KERN (*Surg., Gynecol. and Obstet.*, September 1927, p. 387) discusses cauterization of the cervix which he regards as the most efficient method in early malignancy. Even if the morbid process has extended beyond the level of the cauterization no harm results from the procedure because no living cancer cells have been transplanted. The only instruments required are a heat controlled cauterizing knife, an Oatland's vulsell, a weighted speculum and two ordinary right angled retractors. Insulated or water cooled retractors are not necessary since the heat is in the knife. There is no after pain or haemorrhage during the time of healing, but the patient should remain in bed until the small eschar has separated. The operation is indicated after the climacteric for suspected malignancy with a badly eroded cervix in the presence of early or advanced epithelioma. Since the resulting cauterization closes the uterine canal the procedure should not be employed prior to the climacteric unless it is to be followed by a supravaginal hysterectomy. While sharp traction is being made on the cervix the dull red cauterization is carried along the junction of the vesical fold coming upward toward the canal. This line of cauterization is continued round the cervix at least fifteen minutes being required for its completion. The resulting specimen resembles an acorn in shape. Healing follows rapidly, loose gauze packing saturated with hipp paste being used. The operation can be followed immediately or after a fortnight, by radiation.

### Placentoma Benignum

R. PALAZZO and R. PALLI (*Rev. Sud. Amer. de Endocrinol., Immunol., Quimioterapia*, July 15th, 1927, p. 555) who record an illustrative case state that placental polypus or placentoma benignum was first described in 1839 by Velpeau. The size varies from a few millimetres to some centimetres and it may be pedunculated or not. The shape may be round irregularly cylindrical or conical and the surface is rarely smooth but usually irregular lobular or mammillated. Microscopically it appears to be formed of a whitish tissue of fibrous appearance accompanied by another tissue resembling mucous membrane with numerous blood clots between the two. On histological examination the tissue of the polypus is found to be continuous with that of the uterine mucosa. The authors report the case of a woman aged 39 the mother of six children the youngest of whom was 10 years old. The symptoms were frequent metrorrhagia and fetid vaginal discharge. A diagnosis of submucous uterine fibroid was made and a subtotal hysterectomy was performed. A pedunculated tumour the size of a tangerine orange was found on the posterior superior surface of the uterine mucosa and on hisological examination it was seen to be a placental polypus. Recovery followed.

306 Insufflation of Fallopian Tubes in  
Dysmenorrhoea

G L MOENCH (*Journ Amer Med Assoc*, August 20th, 1927, p 598) discusses critically the value of treating dysmenorrhoea by carbon dioxide insufflation of the Fallopian tubes. He has collected fourteen case reports of patients thus treated, with the following results. One patient had been much benefited by insufflation, another was slightly improved, two were better for one or two months and then relapsed, one, after improving for a month, was worse than before, seven were unaltered, and two were definitely worse. It was found that the pressure used in forcing the gas through the tubes bore no relation to the results. Dysmenorrhoea caused by pelvic congestion, salpingitis, perimetritis, parametritis, periophoritis, prolapsed ovaries, and cervicitis were unbenefited, auto intlexion of the uterus was also unimproved. The only patients changed for the better were those in whom the cervical canal was very narrow, so that the cannula acted as a dilator. Moench concludes that in cases of premenstrual dysmenorrhoea the old method of dilating the narrow cervix is not to be deprecated, and he utters a warning against regarding such cases as being hysterical or neurotic, though he does not deny the existence of psychic dysmenorrhoea.

## 307. Control of Haemorrhage in Placenta Praevia

W KERWIN (*Amer Journ Obstet and Gynecol*, August, 1927, p 189) describes a method of controlling haemorrhage in placenta praevia by tying the uterine arteries through the vagina. A vaginal retractor placed anteriorly holds up the bladder, while a lateral one exposes the right lateral vaginal fornix. The cervix, grasped with tenaculum, is pulled down, back, and to the left, with a large curved needle threaded with plain catgut a ligature is passed round the main trunk of the right uterine artery and tied. The needle is inserted in the upper part of the right vaginal vault just anteriorly to the midplane and craned inward as high as possible to include all the lateral parametrium. On a supposititious clock dial the entrance would correspond to 10, the exit to 8, while 9 represents the position of the artery. The same procedure is carried out on the left side, and when this ligature is tied all bleeding stops. No denudation of the vaginal wall is made and the operation can be completed in a few minutes. The artery need not be exposed, and the safety of the uterus is assured by the upward retraction of the bladder and the downward pull on the cervix. By this method haemorrhage is said to be completely controlled. Kerwin adds that Caesarean section may not be necessary in the treatment of placenta praevia, that hysterectomy for bleeding after delivery is unnecessary, and that the maternal mortality from haemorrhage should be greatly lessened.

## Pathology.

## 308 Site of Infection and Localization of Tuberculosis.

A SÄTA (*Udd Klinik*, August 19th, 1927, p 1259) considers that human phthisis is not due to a simple lung infection from the air, but is the ultimate effect of some infection elsewhere. From experiments on young rabbits he has shown that tubercle bacilli pass through the wall of the intestine by a process of absorption and are soon carried by the lymphatics into the general circulation, after a few days no bacilli can be found in the mucous membrane of the bowel, which shows no signs of any local infection. Similar observations were made by locally infecting the conjunctiva, the throat, and the skin. The author thinks that tuberculous infection is hematogenous in origin. He refers also to the question of superinfection and reinfection by tubercle bacilli. A weak primary infection evokes changes in the body which he describes as exudative and fibrous diatheses, these act as a form of immunization in preparing the system against a further later infection. To test this theory he employs an immunizing agent prepared by finely powdering highly virulent human tubercle bacilli which have lost some of their virulence by being exposed to slight heat and thoroughly dried. This powder was repeatedly administered subcutaneously or by the mouth to a number of growing guinea pigs, others received in similar manner dead tubercle bacilli, and control animals received no immunizing agent. All the animals were subsequently inoculated with living tubercle bacilli. The control animals all died within three months, and of those treated with the powder some died within one month, some surviving longer up to a year. Histological examination of the treated animals showed that they had died from an exudative inflammation of the mucous membranes, the organs were mostly free from tuberculous nodules, which were only rarely found in the lungs. The animals which survived longer showed the typical pathological picture of human phthisis. The author concludes that tubercle toxin,

whether as an active immunizing agent or as an infection, produces firstly an "alteration" (exudative stage), and secondly, a "proliferation" (fibrous growth), and can be conceived as an alterogenic and fibrogenic antigen. Superinfection and reinfection play an important part in the setting up of typical phthisis, previous frequent mild infections of tubercle bacilli are the chief influence in the development of phthisis in later life.

309 *Bacillus fragilis* Isolated from the Blood

L BOELZ, R KELLER, and A KEHLSFELD (*Bull et Mem Soc Med des Hop de Paris*, July 21st, 1927, p. 1184) have isolated *B fragilis* from the blood in three cases of septicæmia (one case of puerperal fever and two cases of acute mastoid infection). The organism, which is a small non motile, non sporing, Gram negative, and strictly anaerobic bacillus, appears on Veillon's medium as small round colonies after a week's incubation, but if ascitic fluid is added to the medium growth occurs after three days. When inoculated in a medium with meat turbidity slowly develops and bubbles of gas appear, the fragments of meat remaining unaltered in colour. The organism grows equally well in broth to which pieces of coagulated white of egg have been added, and there is no digestion of the egg albumen. In gelatin round punctiform colonies appear at about the tenth day, there is no liquefaction of the medium. The bacillus is not pathogenic for rabbits and guinea pigs either by subcutaneous or by intravenous inoculation. The septicæmia in each patient was slight, only a few colonies being isolated from 10 c cm of blood. The isolated bacillus was not agglutinated by the serum of the patient.

## 310 The Gasserian Ganglion in Trigeminal Neuralgia

G O E LIGNAC and J VAN DER BRUGGEN (*Nederl Tijdschr v Geneesk*, August 27th, 1927, p 912) examined the Gasserian ganglion in 22 cases, in 21 of these it had been removed by operation and in one after death. In the operation cases the ganglion was fixed immediately after removal in a 10 per cent solution of formalin, so that any post mortem changes were excluded. The ganglion cells showed loss of staining, atrophy, basophilia and vacuolation of the protoplasm, perinuclear pigmentation, pyknosis, chromatolysis, and karyolysis. The nerve fibres were thickened with balloon shaped swelling of the medullary sheaths, fine or coarse granulations, and loss of staining. In the interstitial tissue there were infiltrations of lymphocytes, plasma cells, and eosinophil leucocytes.

## 311. Bacteriological Examination in Tuberculous Meningitis.

F PARADISO (*La Pediatria*, August 15th, 1927, p 881) reports a case of meningitis where, as is so often the case, the diagnosis was difficult, and emphasizes the importance of the presence of tubercle bacilli in the spinal fluid. He appears to have been more than usually fortunate in finding these bacilli, detecting them in sixteen cases, and he attributes his success to his method of examination. After collecting the fluid with all aseptic precautions he centrifugalizes it immediately for at least an hour, and then stains the film by the Ziehl-Neelsen method. If immediate centrifugalization was impossible the liquid was put in sterile tubes containing a few drops of 10 per cent sodium citrate solution. Of his 16 cases the fluid was removed in the first week in 4, in the second week in 9, and in the third week in 3 cases. Since he has used this method the proportion of successes has risen to 90 per cent.

## 312 Ultra-violet Radiation and Metabolism

MARGARET E. FRIES (*Amer Journ Dis Child*, August, 1927, p 159) denies that there is a rise in basal metabolism following ultra violet irradiations. Three children in hospital were selected and their diet and activities were carefully controlled. After having been trained for a month to use the high basal metabolism apparatus they were exposed three times a week for a month to the ultra violet radiation from a quartz mercury lamp. A suberythema dose was sought, but occasionally a moderate erythema was produced. All the children became pigmented during the course of treatment. The basal metabolism was determined three times a week on alternate days, following irradiations lasting twenty to seventy hours. It was seen that there was no greater variation than 9 per cent—a figure which came well within the limit of error. MARGARET FRIES and ANNE TOPPER (*ibid*, p 165) carried the investigation further by determining the basal metabolism of five hospital children preceding and immediately following irradiations, and again one, two, and six hours later. In these cases also there was no greater variation than 10 per cent in the basal metabolism preceding and following irradiations, except where there was some disturbing environmental factor. The blood pressure and the pulse rate remained almost constant throughout.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine

**313. Etiology of Headache.**  
G. PERITZ (*Med Klin*, August 5th 1927, p 1169) classifies the causes of headache as organic including cerebral tumours, meningitis, hydrocephalus and syphilis and secondly, functional disturbances such as overwork, fatigue, uterine and endocrine irregularities, obesity, intoxication and reflected pain. In the first group the pain is not localized but distributed over the head, sometimes beginning suddenly with in case severity. It depends on the sudden or gradual (in case of tumours) increase of the intracranial pressure, sooner or later the signs of intracranial disease become manifest and are diagnosed. This form of headache is often relieved by the lumbar puncture performed for mild diagnosis. The headache of syphilitic origin is of two kinds: the one markedly localized in the bones and periosteum and often the result of irritation of the nerves of the meninges; the other form is indistinguishable from functional headache and probably also arises from a slight degree of meningitis. Functional headaches are migrainous and of cerebral or meningeal origin. Myalgia is a partial muscular contraction, and the degree of pain is inversely proportionate to the resistance of the nervous system. The muscular contraction causes a production of lactic acid which if the oxygen supply is insufficient to convert it into glycogen and carbonic acid is not removed from the muscle and myalgia results. Fatigue after walking is due to the excess of lactic acid produced in the muscles. The headache of fatigue and overwork is the result of excessive production of lactic acid in subjects of poor muscular development. In anaemia the diminished haemoglobin content of the blood causes deficiency of the supply of oxygen to the muscle and an accumulation of lactic acid. Similarly in gouty persons the myalgia is caused by uric acid the normal removal of which is interfered with, inciting contraction of the muscular tissues and myalgia.

**314. Orchitis due to Varicella.**  
J. SARRAZIN (*Bull Acad de Med* July 26th 1927 p 122) states that though orchitis is a frequent and well known complication of small pox, no example of its occurrence in varicella has hitherto been recorded to his knowledge. He now reports a case in a man aged 20 in whom all other causes of orchitis could be excluded. The complication which developed during the first few days of the disease attacked first the left and then the right testicle and then the left again. Under treatment by rest and sedatives complete recovery ensued. Remembering the close relation between small pox, vaccinia and varicella it is now surprising that orchitis may occur in each of these diseases as it is a common complication of variola and has also been described in vaccinia. In view of the nuclear inclusions which T. M. Rivers found in the testes of the young monkey inoculated with the products of varicellar lesions it would seem that the glands are very receptive of this virus when it has been obtained within the first twenty-four hours of the onset of the disease and inoculated without delay. These nuclear inclusions were not obtained with any material inoculated apart from the virus of varicella nor did they appear when the varicellar virus had been mixed before inoculation with the serum of a patient convalescent from varicella.

**315. Epidemiology of Paratyphoid A Fever.**  
E. P. SANDERS (*Neerl Tydschr v Genees* July 9th 1927, p 177) who records two undoubted and two probable cases remarks that paratyphoid A fever is apparently very rare in Holland although it is possible that some cases have escaped recognition. His four patients had come from Central America where paratyphoid A fever is endemic. A study of the prevalence of this infection shows that it is associated with typhoid fever, and is an expression of bad faecal hygiene. Paratyphoid A fever therefore, is almost unknown in England and Holland and uncommon in Germany in which it is countries the incidence of typhoid fever is low but it is commoner in France, Italy, the Balkans and South Russia where the incidence of typhoid fever is high. Epidemics of paratyphoid infection however die out sooner than those of typhoid fever partly because the bacillus is less resistant and partly because there are far fewer carriers than in the case of typhoid. Moreover paratyphoid A carriers become free from these bacilli more rapidly than typhoid carriers.

**316. Diagnosis of Subacute Bacterial Endocarditis.**  
L. M. HURTHAL (*Loston Med and Surg Journ* July 14th, 1927 p 41) reviews the histories of 65 consecutive cases of subacute bacterial endocarditis from the point of view of differential diagnosis. He found that pulmonary signs and symptoms occurred in over 75 per cent, and he suggests that this may be due to the lodgment of emboli in the nutrient bronchial arteries and gross infarction of the lung, having its origin in the right side of the heart. Clubbing was rarely found in these cases in the absence of a palpable spleen. Hurthall thinks that although positive heart findings are suggestive, their absence should not rule out the possibility of endocarditis. Acute or chronic pericarditis was found in 25 per cent of cases which came to necropsy. Precordial pain was usually associated with an aortic lesion. In all the cases the cardiac rhythm was normal. In most cases it would appear possible to distinguish between true chronic glomerular nephritis and the embolic nephritis of bacterial endocarditis the excessive hypertension of the former being seldom present in the latter. The presence of fever, embolic manifestations and macrophages in the blood with a valvular lesion, clubbing of the fingers, or splenomegaly warrants a positive diagnosis. The most characteristic finding in the central nervous system was a high white cell count without recovery of bacteria from the cerebrospinal fluid—an aseptic meningitis. Summarizing the blood findings, Hurthall considers the presence of macrophages pathognomonic of bacterial endocarditis, while one or two large mononuclear cells with an ingested red cell and their increase with or without vacuolization on smears as the diagnosis. He adds that failure to relieve the pain in the extremities with abeylates in acute arthritis with a rheumatic heart should lead to a suspicion of bacterial endocarditis. Early clubbing of the fingers associated with the presence of blue net print in spots in round the nail margins and tender finger tips is a very suggestive manifestation.

**317. Post diphtherial Paralysis.**  
F. MAJEON (*Il Policlinico Sez Prat* August 15th 1927 p 1172) describes seven cases of post-diphtherial paralysis of illiterate various types. The commonest time for the paralysis to appear is about twenty days after the cure of the local manifestation of the disease but as his cases show it may appear much earlier or later. The paralysis bears no relation to the severity of the local lesion and is more common after the anginomatous type than the larvageal. The most frequent variety is paralysis of the palate and pharynx next in frequency is a general asthenia and loss of the patellar reflex. The author mentions some of the paralytic due to other causes which may give rise to difficulty in diagnosis. The administration of serum is recommended and the trial of several strains until definite results are obtained.

## Surgery

**318. Gastric Tuberculosis.**  
G. BLANCHI (*Il Morgagni* August 7th 1927 p 124) comments on the rarity of tuberculosis of the stomach both relatively and absolutely in spite of the frequent introduction of the bacilli into the stomach with the food swallowed saliva and expectoration and from the blood and lymphatic channels, the organisms only rarely becoming attached and developing in the wall. This comparative immunity of the gastric wall is variously attributed to the constant movement of the stomach contents to the high contractility of the muscularis mucosae to the inhibitory nature of the gastric juice as a medium for the development of the tubercle bacillus or any micro-organism (though the hydrochloric acid of the gastric juice is not in itself antiseptic and also a proteolytic agent on the mucus secreted by the gastric epithelium). The author considers that primary gastric infection though very rare is not impossible but infection secondary to tuberculous lesions of the lungs and glands is more common being brought by the lymphatics from the neighbouring infected glands. The gastric mucous membrane the serous membrane of the peritoneum, and from the blood. Clinical and therapeutic details are given of two cases in which gastric tuberculosis was confirmed by laparotomy. In one case there were physical signs in the left pulmonary apex a globular swelling on the small curvature of the stomach, and a histologically typical

tuberculous gland in the gastric hepatic ligament close to the gastric tumour. In the other case the symptoms were confined to the stomach, and the condition was diagnosed as ulcer of the smaller curvature. Laparotomy showed a fixed globular swelling infiltrating the smaller curvature, and histological examination of an enlarged gland adjacent to the stomach showed unmistakable tuberculous structure.

### 319 Operative Treatment of Chronic Otitis Media

F. B. GILHESPI (*Journal of Laryngol and Otol*, August, 1927, p. 520) reports a series of thirty-four cases of chronic suppurative otitis media in children under 14 years old, all had failed to yield to long courses of treatment, including irrigation. He therefore resolved to try the effect of operative treatment. In seven cases the Schwartz operation was performed, resulting in six dry ears from nine operations. In ten cases the conservative mastoid operation was employed and was followed by seven dry ears. The indication for operation in another series of seven cases was attic perforation and discharge, in all these the mucus was removed so as to obtain better drainage, and the hearing did not appear to suffer. In seventeen cases the radical mastoid operation was performed with nine successful results. The author is impressed with the desirability of a large meatal opening and the cutting of a flap from the posterior meatal wall, he considers that packing should not be continued too long. During the twelve months previous to this report thirty-seven cases of chronic suppurative otitis media in children were treated surgically. Thirty-one radical mastoid operations resulted in dry ears in twenty-two cases, two conservative mastoid operations were performed successfully, and three Schwartz operations resulted in only one dry ear. The author is disposed to advocate less radical procedures, and finds that his results have been improved thereby. He now restricts the conservative operation to those cases which have attic perforation and suppuration.

### 320 Agranulocytosis Complicating Cholecystitis

EDITH PERITZ (*Zentralbl f. Chir*, August 20th, 1927, p. 2129) refers to the numerous cases of agranulocytosis (diminution of the granular leucocytes) that have been recorded recently and notes that all future cases should be published in view of the difficulty of differential diagnosis. Agranulocytosis comes on suddenly with pyrexia. The essential symptom is tonsillar and palatine necrosis resembling diphtheria, but without bacteriological findings. Ulceration of the vaginal mucosa is always present in female patients. The prognosis is unfavourable. She reports the case of a woman, aged 47, with a history of frequent attacks of pain in the right hypochondrium for seven years. In August, 1926, and February, 1927, she had typical attacks of biliary colic, with pain radiating to the right shoulder, vomiting, rigors, and slight jaundice. On admission to hospital slight tenderness in the right hypochondrium, with resistance, was detected. The urine contained albumin and urobilinogen, but no sugar. The sediment consisted entirely of scattered red corpuscles and granular casts. There was nothing objective to account for the rapid pulse and fever. A diagnosis of cholangitis was made. The hypertrophied tonsils showed punctate folliculitis, there was a yellowish white ulcer on the dorsum of the tongue and numerous whitish ulcers were present on the vulva. A blood count showed 3,000 leucocytes per c mm, which were chiefly lymphocytes, the characteristic picture of agranulocytosis. The patient died next day, the leucocyte count having fallen to 800. The necropsy confirmed the diagnosis as the primary disease was a chronic cholecystitis with gall stones. There were small necroses in the liver which may have accounted for the indefinite pains in that region.

### 321 Surgical Collapse of the Lung

A. A. LAW (*Annals of Surgery*, August, 1927, p. 227) asserts that the cure of unilateral pulmonary tuberculosis can only be accomplished by causing collapse of the organ. In 80 per cent of cases this can be produced by artificial pneumothorax. In the remaining cases collapse is prevented by adhesions, and the operation of paravertebral extrapleural thoracoplasty offers the only possible chance of overcoming this difficulty. In a series of 91 operations complete collapse was not obtained in 8 per cent of the cases. Phrenicotomy is useful in cases where the patient is too ill to permit the longer procedure or where after thoracoplasty the base of the lung has failed to collapse. Avulsion of the phrenic nerve has been tried in later cases and is better, as it tears the accessory branches and assures paralysis of half the diaphragm. X-ray studies show that after these procedures the collapsed lung is at rest and non-functioning, 36 per cent of cases are cured and 24 per cent improved by this operation, which therefore appears worth consideration in the case of patients for whom there is no hope otherwise.

## Therapeutics.

### 322 Medical Treatment of Duodenal Ulcer

D. VANDERHOOF (*Journal Amer Med Assoc*, July 30th, 1927, p. 344), drawing attention to the inefficiency of surgical treatment in chronic peptic ulcer, maintains that practically every case of uncomplicated duodenal ulcer is curable by adequate medical treatment. Peptic ulcer occurs much more frequently in the first portion of the duodenum than in the stomach, and in many instances it is uncomplicated either by periduodenal adhesions or by disease in the appendix or gall bladder. The most important part of treatment is frequent feeding, in patients with severe pain and marked pylorospasm the ideal food is stated as 2 oz each of cream and sweet milk with 10 grains of sodium citrate, given once every hour from 7 a.m. to 9 p.m. In the average case six feedings a day suffice, but no more than three hours should elapse without feeding. Except in acute cases and those with haemorrhages a liberal diet is given with avoidance of all acids, raw fruits, soups and meat extracts, condiments and spices, intense sweets, very coarse foods, and alcohol in any form. Fatty foods, such as cream, butter, and olive oil are best for patients with ulcer, while different forms of albumin, as milk, eggs, and cooked meats, are also recommended. The administration of atropine or holladonna is useful in relieving pylorospasm and hyperperistalsis, and possibly in reducing the total gastric acidity. The author gives ten drops of tincture of holladonna in water three times a day before the regular meals. After these meals a level teaspoonful of lithium subcarbonate is administered, if this proves constipating a small amount of heavy magnesium oxide may be added. This treatment, in order to effect cure, must be continued regularly and persistently for two years, and intelligent co-operation by the patient is necessary. Any physical impairment (tonsillar, sinus, or dental infection) should be corrected, and cases of chronic appendicitis or cholecystitis treated surgically before the ulcer treatment is instituted. At the end of two years all medication is discontinued, and the patient allowed freedom in diet, though the foods already mentioned should still be avoided or only sparingly taken. Vanderhoof emphasizes that successful results depend chiefly on the intelligent co-operation of the patient, and on continuing the treatment daily with regularity and persistence for two years.

### 323 Haemostatic Action of X Rays

L. POPP (*New York*, August 11th, 1927, p. 1029) describes four cases of obstinate epistaxis which were treated by the application of small doses of x-rays (focal distance from the skin 23 cm, flash 30 cm, filter 5 mm aluminium) over the region of the spleen, the haemorrhage being stopped in each case. This effect of x-rays is explained as being the result of an overproduction of thrombocytes other than the reticular endothelium of the spleen or from the destruction of white blood corpuscles. It has long been known that by stimulation of the bone marrow by x-rays the number of the blood platelets is raised with a resulting increased amount of coagulation ferment, and the method has been successfully employed in haemophilia and in cases of severe purpura. The effect of x-rays in haemorrhagic diathesis persists for only a few days, but the arrest of the haemorrhage enables further medical treatment to be applied. The application of x-rays has been used in cases of metrorrhagia and menorrhagia, and it is also recommended twenty-four hours before operations likely to be accompanied by severe haemorrhage. Beneficial results are said to have been obtained by the application of x-rays to the spleen in cases of thrombopenia and icterus haemolyticus.

### 324 Synthalin in Diabetes Mellitus

I. M. RABINOWITCH (*Canadian Med Assoc Journal*, August, 1927, p. 901) refers to the literature and reports some personal cases of diabetes treated with synthalin or butylamine guanidine, a substance capable of aiding carbohydrate metabolism when given by the mouth. In one case it appeared that 10 units of insulin could be replaced by 25 mg of butylamine guanidine. Staring success was obtained in the case of a man, aged 48, who was having 25 units of insulin daily. The insulin was gradually replaced by synthalin till he was taking 50 mg of this daily and kept his sugar free in spite of the insulin having been discontinued altogether. On three occasions he had abdominal cramp and nausea, and the blood sugar once rose above normal when he had a cold. The results of treatment of six carefully selected cases, all requiring an average of 10 units of insulin per day, are recorded. Two were completely successful, one patient is keeping sugar free with occasional relapses, one case was unsuccessful from the start, and two patients became sugar free for one and two months respectively and

then relapsed. In all cases the average body weight was less during the administration of synthalin than with insulin. In one patient, treated so far only for one month 25 units of insulin daily have been gradually replaced by synthalin; the author reports one complete failure in a case where this preparation was given four days after recovery from coma. In three cases where 50-mg. doses were being given daily gastro-intestinal disturbance occurred on the fourth day, and the blood gave an indirectly positive van den Bergh reaction. The author found that such effects were more easily avoided by administering the drug for two days and then allowing two days' rest before the next dose. Liang had suggested that patients might acquire tolerance to the gastro-intestinal disturbances, and had suggested the analogy of the effects of nicotine. Rabinowitch considers synthalin effective in diabetes mellitus, but advises that until more is known about the dose and the optimum time for administration its use should be restricted to hospitals, where its effects can be properly observed.

## Radiology

### 325. Radium Treatment of Oesophageal Cancer

Dr. ABRIUS (*Journ. de l'Incol et de l'Electrol.* June 1927 p 332) describing his special technique for radium applications in oesophageal cancer says that there is a great disproportion between the size of the lesion which is often small and the enormous mass behind and around the oesophagus in the posterior mediastinum and that radium placed merely in the oesophagus is incapable of affecting such a mass. According to him there are four essential points in radium therapy: (1) treatment simultaneously of the lesion and the lymphatic territory; (2) the area involved must be approached from the periphery and not from the centre; (3) application to all points of the region to be treated of the equivalent of 2 mg. of the radium element; (4) maintenance of this dosage for a period corresponding to the intensity of the radioactive activity of the tumour. By his method the radium can be applied either posteriorly or anteriorly. In the former case the oesophagus is close to the posterior wall and the neoplastic mass, extending greatly beyond the vertebrae, can be easily treated by means of two lateral appliances placed vertically on each side of the spine. The electrode should extend for at least the breadth of a vertebra beyond the upper and lower limits of the lesion and contain 10 mg. of radium filtered through 2 mm. of platinum and placed 3 cm. apart and 3 cm. from the skin. The dose is the same in anterior applications and here the appliances should extend beyond the sternum and the lesion and should reach from above the manubrium sterni to the xiphoid cartilage and at least three fingerbreadths from the lateral borders. In this appliance the tubes of radium are placed in series of fives. Anteriorly the vertebral bodies and posteriorly the sternum ribs and cartilages, form screens impenetrable to the rays and to compensate for this loss of radiation it is necessary to insert intra-oesophageally tubes containing 10 mg. of radium which extend for the whole length of the lesion. These tubes need be retained for only five days, and should be applied in the middle of the total treatment, which lasts twenty-five days. A case treated successfully with posterior applications is described.

### 326. Treatment of Burns due to Heliotherapy

In the treatment of lupus vulgaris with Kromayer's lamp the length of exposure without filtration is according to J. M. WYDOOGHE (*Bruzelles Med.* July 17th 1927 p 1191) from five to twenty minutes, while this is sufficient to destroy superficial tumours this short irradiation is inadequate to affect deep lesions. The duration of exposure is limited by the action of the rays upon the skin, an irradiation (with compression and without filtration) of twenty to thirty minutes causing lesions comparable with burns of the second degree. At the site of application intense burning sensations are felt, the skin becomes inflamed and oedematous blisters form the central portion necroses with scar formation and whatever the subsequent application may be cure is tardy and tedious. The author mentions the usual agents used in the treatment of burns and points out that these are either antiseptic, analgesic, or keratoplastic and that a substance combining all three properties is rare. Among the new preparations this tried was scaevoline, a para amino benzoate of butyl. This is a liquid with a peculiar odour a density of 1.050 soluble in all proportions in olive oil acetone ethyl and methyl alcohols, ether chloroform, and acetic acid but only slightly in water and glycerin. It is analgesic markedly antiseptic, and keratoplastic and has been used by Wydooghe with great benefit in the burns caused by Kromayer's lamp. Owing to these properties the repair of the tissues is aided, and a rapid almost painless, scar is obtained. Moreover, by the use of scaevoline longer exposures, even of an hour, can

be made without ill effects thus permitting a more intensive treatment of the lupus. The drug is used in ointment form in a strength of 10 per cent.

### 3-7 Pyelo ureterography

V. J. O'CONNOR and A. REMBERT (*Radiology* August, 1927 p 129) discuss the value of pyelo ureterography as an aid in diagnosis, with a review of 356 cases in which 627 pyelo ureterograms were studied. Complete reduplication of the renal pelvis was found in 48 instances and considerable variation in the outlines of the normal pelvis was seen. This indicated the importance of being thoroughly familiar with the variations in order to interpret accurately the early distortions which may accompany renal neoplasms. A right hydronephrosis occurred in 45 instances, a left in 13 and bilateral in 9. In 110 cases of renal tumour showed typical displacement or contraction of the pelvis with narrowing and elongation of the calyces and the authors think that considerable experience in interpretation is necessary before the possibility of early tumour can be excluded in some cases. In renal and ureteral calculi the pyelo ureterogram was of great assistance in determining treatment and prognosis. Out of 36 cases of renal ptosis no angulation of the ureters and no dilatation of the pelvis or calyces were present in 19 while 15 showed definite ureteral kinking and angulation. In 111 instances a diagnosis of ureteral obstruction or stricture was made on the ureteral outline, and the authors are convinced that definite contraction with dilatation above the narrowing will be made evident by careful ureterography. In 12 cases it was possible to eliminate the kidney as the cause of a palpable mass in the flank or abdomen and such negative evidence was of assistance in the differentiation of abdominal or retroperitoneal masses. The procedure was never followed by anuria, sepsis or severe reaction. While recognizing the diagnostic value of pyelo ureterography as now performed under improved technique the authors emphasize the fact that it is only to be regarded as one of the valuable urological aids to accurate diagnosis and that it should not be used except in conjunction with all the other available investigations.

### 328. Diathermy of the Tonsil

G. A. DILLINGER (*Med. Journ. and Record* May 13th 1927 p 659) reports the results of using electro coagulation of the tonsils in a series of 150 cases necessitating nearly 1,600 separate treatments. He strongly recommends this procedure as a substitute for tonsillectomy. A machine giving 1,750,000 oscillations per second supplied 2-60 milliamperes. It was connected with a piece of black tin 6 in. by 10 in. placed on the skin of the patient's head. The soft palate tonsil inside of cheek and the base of the tongue were anaesthetized by the application of four or five drops of a 10 per cent solution of cocaine repeated five or six times with pledgets of cotton wool each used only once. The needle was then inserted from one eighth to one-quarter of an inch into the tonsil and the current switched on for from one to two seconds until a white ring appeared round the needle indicating that the point of coagulation had been reached. The procedure was repeated until the tonsil had been covered with punctures about a quarter of an inch apart. After painting with acrif violet the patient was able at once to carry on his usual occupation. Dillinger advises that only one tonsil should be treated at a sitting two or three applications to each tonsil being given at intervals of about eight days. He considers this preferable to attempting to remove both tonsils at one sitting. He concludes that by carrying out the proper technique and only treating one tonsil at a time at two or three sittings success is certain without any danger to other structures, or the risk of any of the objectionable features of tonsillectomy. He advocates a similar technique for the treatment by diathermy of chronic tonsillar ulcers, stricture of the larynx, tumours of the throat and tongue, and lupus of the face.

## Obstetrics and Gynaecology.

### 329. Puerperal and Abortion Sepsis.

E. R. WHITE (*Med. Journ. Australia* July 19th 1927 p 33) records observations upon 70 patients suffering from puerperal sepsis and 285 from infection following abortion. Bacteriological examinations of smears and cultures from the cervix and uterine cavity were made in 50 consecutive cases and streptococci were found in 45 per cent both within and without the uterus. In the acute blood infections and in most cases of severe local sepsis haemolytic streptococci were almost invariably present. In 25 mild sapraemic cases organisms usually *Streptococcus viridans* were found within the uterus and on the cervix in 35 per cent. Non haemolytic streptococci were commonly present both before and after

delivery in normal patients, in 28 per cent of the cases these caused local puerperal sepsis as a definitely endogenous infection. The author considers that severe sepsis is generally an exogenous infection, being caused mainly by haemolytic streptococci, which are seldom found before delivery. An endogenous infection by haemolytic streptococci may cause puerperal sepsis in association with gonorrhoea, erosion of the cervix, recent coitus, or a blood borne infection from an extrauterine focus. White believes that by abstaining from intervention and by the prevention of exhaustion and loss of blood much may be done to prevent infection, intrauterine procedures, except for haemorrhage, are contraindicated. General treatment aims at increasing the natural powers of resistance by vaccine or serum administration and blood transfusion. He advocates the intravenous injection of mercurochrome 220 in order to kill any organisms in the blood stream, thus converting a septicaemia into a condition of local sepsis with a more favourable outlook, he claims that this has proved to be of definite value in treatment.

### 330 Uterine Peristalsis and the Ovarian Cycle

DYOFF (*Zentralbl. f. Gynak.*, July 30th, 1927, p 1950, Meeting of German Society of Gynaecologists, No 7) has studied peristalsis in the uterus and Fallopian tubes by taking x-ray photographs after injecting an opaque oil without using pressure, thus ensuring normal physiological conditions in the organs. He finds that the degree of peristalsis in uterus and tubes depends on the ovarian cycle, it is increased toward the end of the interval and the movement of anything within the organ is accelerated. Peristalsis also influences the formation of the peculiar constriction which appears at the uterine end of the tube, and which the author considers as belonging to the uterus and not to the tube. During the first half of the intermenstrual interval the tone of the uterus and tubes is raised and their capacity lowered, there is no evidence of peristalsis, and emptying is much slower. Similar conditions were observed in movements of the tubes. Opportunity was taken of laparotomies to introduce the opaque oil into the abdominal ostium of the tube, and serial photographs were obtained of its progress. During the premenstrual period the oil took only four and a half days to reach the uterus. During the postmenstrual time the oil had not left the tube eight to fourteen days later, indicating that transmission of the ovum depends on the menstrual cycle, and that it is hastened only at the end of the second half. This activity of the tube is directed by the corpus luteum, but other conditions also influence it—in particular, reflex peristalsis during coitus. Dyoff concludes that there is no definite duration for the movements of the ovum, and that it depends on various physiological conditions.

### 331 Lacerations of the Cervix during Accouchement

E COUDERT (*Journ. de Med. et de Chir. Prat.*, July 10th, 1927, p 460) divides cervical lacerations into subvaginal, which are very frequent, benign, and seen in primiparae, and combined sub and supra vaginal, which may extend to the lower uterine segment, are rare and sometimes very serious, and are seen more especially in multiparae. These lacerations may be either spontaneous (maternal or foetal) or traumatic, the latter being much the more frequent. The cervix ruptures spontaneously when there is a disturbed equilibrium between the uterine contractions and the cervical dilatation, due either to excessive contractions or to an abnormal resistance of the cervix to the uterine efforts. A slow labour with a difficult presentation causes oedema of the cervix, which loses its elasticity, becomes less resistant, and facilitates the production of lacerations. Very important causes of cervical tears are cervico vaginal cretations following previous confinements. Traumatic lacerations often follow interventions (dilatations, forceps applications) for foetal extraction before the cervix is completely dilated. Cervical lacerations are linear, occur usually laterally, and generally on the left side only, if extensive the uterine artery may be ruptured, though generally only its cervico vaginal branches are affected, and neighbouring organs, such as the broad ligament, rectum, and bladder, are seldom involved. Diagnosis is said to be easy, a hard, retracted, low uterus, instead of a soft, large organ, together with persistent haemorrhage, indicate a laceration. Prognosis depends on the place and extent of the lesion. Benign lacerations of the lower part of the cervix heal rapidly, supravaginal ones, especially if accompanied by severe haemorrhage, are more serious, and death may supervene. Remote ill effects are cystitis and uterine displacements. Lacerations can be largely avoided by slow conduct of labour, care being taken that the cervix is fully dilated before there is any intervention. If haemorrhage occurs it may be controlled by manual compression, and, failing this, by either introducing tampons into the uterus and vagina or by suturing the bleeding point. If the haemorrhage persists and is severe laparotomy is necessary.

## Pathology.

### 332 The Fixation of Foreign Bodies by the Omentum

PERIOT, ROUSLACROIX, and M ARNAUD (*C. R. Soc. de Biologie*, July 22nd, 1927, p 577) injected Chinese ink or grains of carbon into the peritoneal cavity of guinea pigs, and followed the results by laparotomy at regular intervals. They found that the whole of the foreign matter was fixed by the great omentum, the peritoneal peritoneum, the peritoneum covering the intestines, and the mesenteries were absolutely free. The granules were rapidly taken into the interior of the omentum, where they were absorbed, not by the lymphatics or capillaries, but by the fixed cells. These cells were in fact transformed into masses of black. When very large injections were made, the material that could not be dealt with by the great omentum was taken up by the small omentum and by the serosa on the posterior surface of the stomach, whence it made its way to the pancreas and retroperitoneal glands. The granules remained in the great omentum indefinitely, and even after six months it was still tattooed black, the lesser omentum and the gastric serosa, on the other hand, become progressively decolorized. When ampoules or capillary glass tubes (ibid., p 579) were introduced into the peritoneum, the great omentum sent prolongations into them. Accompanying this there was a rapid proliferation of fixed cells and a formation of new capillaries. This hyperplastic process was so marked as to convert the tubes into veritable cultures of omental tissue.

### 333 The Effect of Heat on Antibodies

T S JONES (*Journ. Exper. Med.*, August 1st, 1927, p 291) finds that certain types of agglutinins respond differently to varying temperatures, and that it is also possible that heat so affects some of the serum proteins that they no longer react in the characteristic manner. Rabbits immunized to various substances were bled and the serums stored. These, containing agglutinins and haemolysins, were diluted with four parts of normal saline and heated at different temperatures. Flagellar and somatic agglutinins were readily separated by exposure to 75°C for twenty minutes, the somatic strain not resisting this heating, whereas after exposure to 80°C and even to 90°C the agglutinins of the flagellar type still persisted. That the agglutinins were no longer present in the inactivated serum was shown by the failure to reactivate on addition of fresh normal rabbit serum. Jones finds that antibody destruction continues gradually as the temperature is raised, heating to 65°C for twenty minutes affects the activity of all antibodies with the exception of red cell agglutinins, and with these, though the end titre was the same, some antibody was inactivated, since the reaction was weaker in higher dilutions, when the temperature is raised to 80°C red cell agglutinin is completely inactivated, but sufficient haemolysin still remains to give a slight reaction at the lowest dilutions, though all haemolysin is destroyed at 85°C. Somatic agglutinin and precipitin are both diminished when heated to 65°C, at 70°C the agglutinin is further diminished though not the precipitin, but at 75°C both are completely inactivated. The author adds that no comparison can be made between similar antibodies in the serum of different species, somatic agglutinins in rabbit serum resisted a temperature of 70°C for twenty minutes, though the same agglutinin in cow serum was destroyed at 65°C.

### 334 Etiology of Chronic Intestinal Auto Infection

In a series of eighty five cases of chronic intestinal infection P DESGEORGES (*Rev. de Med.*, 1927, No 2, p 163) has identified, by culture from the mucus collected with all precautions, *B. coli* sixty nine times, the enterococcus ten times, in five cases both *B. coli* and the enterococcus, and in one case in association of *B. coli* with *B. paratyphosus*. He finds that the organisms pass from the mucosa of the caecum, not by the portal vein, but by the lymphatics to the thoracic duct, and thence into the general circulation. He considers that if the organisms passed by the portal vein directly to the liver they would be eliminated with the bile before entering the circulation and would only rarely appear in the urinary passages, they reach the liver by way of the hepatic artery. He believes that the essential factor in the production of chronic auto infection is the low virulence and slow rate of multiplication of the organisms, which explains the rarity with which cultures can be obtained from the blood in these cases, those which are not destroyed in their temporary passage in the blood are soon eliminated by the liver and kidneys. In a sensitive subject the bacteria, if sufficiently numerous, give rise to symptoms caused partly by their toxins, but also by their bodies acting as a foreign albumin—protein of an anaphylactic nature. The various predisposing causes of auto intoxication are constipation, chronic appendicitis, intestinal worms, abuses of diet, and irregularities of liver and bile secretion. The author discusses the symptoms, sequelae, and treatment of the condition.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine

### 335 B. coli Infection of the Digestive System

H. MATHIE (*Presse Méd.*, August 17th 1927, p. 617) describes a case of acute infection of the digestive tract simulating typhoid or paratyphoid fever but due to *B. coli*. He suggests that the increased fecundity of this disease may be due to an increased virulence of the *B. coli* bacillus or the triple (LAB) vaccination by diminishing the typho-paratyphoid factor may bring the infection into prominence. Mathie previously reported diseases of this condition in which patients of *B. coli* were obtained from the blood. He now records three further cases in one of which the blood was positive for this organism but was negative in the other two in which the bacillus was recovered from the urine collected under the strictest precautions to avoid contamination. These attacks are characterized by a complete acute picture similar to that in typhoid fever, a rapid pulse, headache, malaise and vomiting. Either diarrhoea or constipation may be present rose-colored spots may be seen and the spleen may be enlarged. The author states that *B. coli* is the cause of infectious rash, from typhoid to a more febrile acute disturbance, and that when blood cultures are negative the urine should be examined for the causative organism. He adds that cases should not be diagnosed as typhoid or paratyphoid fever without this precaution having been taken.

### 336 Haemoptysis in Tuberculosis

L. BAIRD (*Presse Méd.*, August 17th 1927, p. 1003) distinguishes four clinical types of tuberculous haemoptysis: (1) the sequel of an abortive lesion and an index of favourable prognosis; the haemoptysis is unaccompanied by cough, two presymptomatic cases of dry cough, fever or pain. This type was named by Brabantou mechanical haemoptysis. (2) The most common type is characterized by a sputum more or less haemorrhagic in character and associated with the inflammatory exudates of alveolitis. The condition resembles that in lobar pneumonia and is produced in a similar way: there is blood in the sputum but not a true haemoptysis. (3) A type following the rupture of ulcerated arteries: the active focus of the disease or in cavities. (4) Congestive or inflammatory haemoptysis: a rather more complex condition occurring like type (2) in tuberculous alveolitis, the blood comes directly from the capillary net work under the influence of inflammatory vaso-dilatation. The liquid vascular exudation exceeds the catarrhal pericardial proliferation just as the congestive element sometimes outweighs the hepatization in lobar pneumonia. In haemoptysis of the third and fourth classes absolute rest is prescribed in the horizontal position on the back without distinction of the point of origin of the haemorrhage. In the last type however the author advocates lateral decubitus on the side opposite to that in which the bleeding is occurring and quotes a striking instance of cure in a patient treated by him twenty years previously. Since then he has had many cases in which this simple method has proved efficacious. He adds that this treatment suits all congestive cases but especially those due to passive vaso-dilatation.

### 337 Diphtheria in the Federated Malay States

ACCORDING to W. FLETCHER (*Bull. Inst. Med. P. S. Fed. Malay States*, 1927, No. 2) diphtheria was a very rare disease in the Malay States before 1916 and though it is much more common now it does not occupy a prominent place in Government reports as one of the important and serious diseases of the country. Since there have been no severe outbreaks such as might have been expected to follow the introduction of a new disease into a susceptible community. The disease is spread by carriers of whom there are probably more than a thousand in Kuala Lumpur which has a population of 100,000. With one exception all the convalescent carriers have been either Malays or Eurasians such carriers are probably common among Asiatics but it is difficult to trace them after they have left hospital. Schell tests showed that the population was highly immune to diphtheria, the proportion of susceptible children in the schools of Kuala Lumpur being about the same as in the schools of New York. As in America and elsewhere the children of wealthier parents are more susceptible than the children of the poor. The incidence of diphtheria affords additional evidence of its endemicity and consequent im-

munity of the population. In an unprotected community all classes suffer but adult cases are rare in the Asiatic population of the Malay States. The immunity of the population is probably due to the large number of immigrants from China, India, Ceylon and other parts of the world who have been struggling to the country for years and must have brought the diphtheria bacilli with them. The immunity may also have been provided by diphtherial inflammation of other parts of the body than the fauces and nasopharynx. Examination made by Fletcher showed that there was no evidence that the local bacilli strains were less virulent than those isolated in other countries. The recent increase of diphtheria is attributed to the large number of female immigrants and the subsequent increase of the child population.

### 338 Diagnosis of Small pox

A. C. PUIS (*N. Engl. J. Med.*, July 16th 1927, p. 279) has recently employed the following skin reaction in allergic guinea pigs for the diagnosis of small pox as suggested by C. H. J. L. Inche was the first to discover that after vaccination there was allergy—that is an accelerated and weakened reaction notably to vaccine lymph but also to small pox. C. H. J. applied this method to guinea pigs and found that twenty-four hours after vaccination the animals showed a distinct allergic reaction on inoculation both with vaccine lymph and small pox material at various trichloroacetic subcutaneous injection of diluted vaccine lymph from three different sources to eight white mice. After twenty-four days they were inoculated cutaneously with vaccine lymph small pox material and fluid from varicella vesicle control inoculations with glycerine being used in each case. Five guinea pigs reacted to inoculation with vaccine and small pox material but showed no reaction to inoculation with varicella fluid or glycerine. The guinea pigs which showed no reaction were given another subcutaneous injection of vaccine lymph and tested nine days later with vaccine lymph and small pox material when they all showed an allergic reaction. A third test was made a week afterwards when in addition to a distinct allergic reaction caused by inoculation of the vaccine and cow pox material there was slight redness at the site of inoculation of the varicella crusts though there was a distinct difference from the well marked reaction caused by the vaccine lymph and small pox material. It is concluded that this method may be useful for diagnosis in countries where small pox is endemic but PUIS adds that a large series of tests will have to be performed before its value can be established.

## Surgery

### Tuberculosis and Appendicitis

339 PEREPA (*La Méd. Lib.*, August 13th 1927, p. 125) states that the following varieties of tuberculosis of the appendix may occur: (1) The localized form in which the lesions are situated at the base of the appendix or some other point and transform it into a closed cavity. (2) The entero-peritoneal type which is the most common variety and is not infrequently primary. (3) The pseudo-neoplastic form which occurs when the appendix is involved in tuberculous of the caecum. (4) Cold abscess: this is not exceptional, and presents the usual characters of such a lesion. It is very often affected secondarily by pyogenic organisms. (5) The hypertrophic form is due to considerable far-reaching thickening of the walls of the appendix. (6) The atrophic form is very frequent and results from extensive lesions in the neighborhood with or without inflammation and ulceration causing amputation of the appendix. (7) The cystic or hydro-appendicular form is rare since it involves the aspic retrocession of an abscess.

### Diverticulum of Bladder

340 D. M. DAVIS (*Journ. Amer. Med. Assoc.*, July 16th 1927, p. 192) describes an unusual case and method of operation of pre-umbinary diverticulostomy in diverticulum of the bladder in a man aged 75, with symptoms of distension and urinary obstruction due to an enlarged prostate. Catheterization failed owing to arrest in the prostatic urethra. An operation for drainage revealed a very distended organ with thin walls which was thought to be the bladder it contained three

large stones. Cystoscopy later through the suprapubic fistula showed a large diverticular orifice in the right lateral wall, and on passing the cystoscope through it more calculi were found in the second viscus, which proved to be the bladder itself, of which the first cavity was the diverticulum. At a second operation the diverticulum was drawn upward with a Young's prostatic tractor opened out within it, after dissection it was cut off flush with the bladder, the opening into which was enlarged for the removal of two more calculi and the prostate. About seven weeks later the patient was walking about, and he left hospital with perfect control. Davis considers that when the cystogram shows that the diverticulum approaches the mid line it is better to perform diverticulostomy than cystostomy whenever preliminary bladder drainage is indicated, and, further, that the case shows what surprising results can be accomplished in the most unfavourable risks by careful preliminary treatment to render the patient equal to the stages of the procedure contemplated.

### 341 Heart-block after Thyroidectomy

E SIMON (*Zentralbl f Chir*, August 13th, 1927, p 2060) enumerates the heart complications that are associated frequently with goitre, and the effects of surgical intervention on these. He states that although the danger of accidental division of the pneumogastric is small, since it lies normally behind the carotid sheath, this accident may occur in operations on malignant or other deeply seated tumours, but its consequences are usually not so serious as when the nerve is accidentally crushed with forceps or included in a ligature, when fatal syncope may occur. Other signs of vagus irritation are spasmodic cough, with dyspnoea, prolonged alterations in cardiac rhythm, and even fatal apnoea, it may cause bronchial spasm and oedema, while pulmonary congestion is a common sequel. Postoperative pneumonia is not always a result of vagus irritation, but it is due doubtless to the anaesthetic in most cases. When serious heart symptoms occur after the removal of a very large goitre, Simon attributes them to mechanical irritation of one or both vagus nerves during the operation. The patient exhibits characteristic disturbances of the respiratory rhythm which may be followed by bronchitis or pneumonia. Simon concludes that under normal conditions the vagus is not injured in the course of a thyroidectomy even when the anatomical relations are changed. A goitre may displace the vagus considerably, and also the recurrent laryngeal nerve, but the cervical sympathetic is usually unaffected since it lies in a separate fascial sheath. Recurrent laryngeal paralysis is very unusual in ordinary thyroid enlargements, though more common in malignant cases and in inflammatory swellings or haemorrhages in ordinary goitres. The thyroid endocrine secretions are held to be more probably responsible for the occurrence of cardiac disturbances than purely mechanical causes. If serious cardiac symptoms such as bradycardia, arrhythmia, fibrillation, or possibly heart block, occur after a severe and extensive operation, the possibility of vagal injury must be borne in mind, and atropine should be administered at once.

### 342 Subfascial Haemorrhage of Thigh

W R HURLEY (*Boston Med and Surg Journ*, August 18th, 1927, p 261) calls attention to the fact that with only slight external signs of injury traumatism of the thigh may result in a profuse haemorrhage from a torn vessel beneath the deep fascia. The blood may track along muscle and fascial planes and extend in some cases to the extraperitoneal pelvic tissue and the prevesical space. Four cases from the literature are cited, and details are given of a personal case of a boy, aged 8, who was knocked down by a truck. Beyond the discovery of multiple abrasions on the arms and legs and an extensive one on the right thigh the examination was negative, but a few hours later the thigh became swollen, and ten hours after the accident the boy became restless, with marked pallor and pain in the lower mid and right abdomen above Poupart's ligament. At the operation there was no evidence of injury to any viscus, but the peritoneum of the entire right side of the pelvis was raised from its attachment and the prevesical space was distended by blood. In the thigh blood was found spouting from a vessel in the torn semitendinosus with general oozing from injured muscle. The bleeding points were ligatured and the severed ends of the muscles brought together, and though severe shock lasted for several days recovery eventually followed. Hurley points out that in cases of thigh injury the condition of the patient, particularly as regards pulse and respiration, requires careful watching, exploration of the thigh should be undertaken if symptoms of internal haemorrhage supervene with increase in the size of the limb and the presence of tenderness and tension.

## Therapeutics.

### 343 Treatment of Nervous Indigestion

W C ALVAREZ (*Journ Amer Med Assoc*, August 6th, 1927, p 440) considers the treatment of the functional disorders of digestion by psychotherapy with instruction in mental and physical hygiene, physical therapy including exercise and massage, diet, and drugs. He states that a complete physical examination is often the best way to apply psychotherapy, it is essential that the diagnosis should be correct before a patient is treated for nervous indigestion and the assurance is given that there is nothing organically wrong. A thorough understanding must be obtained of everything in the history likely to cause a nervous basis before such measures as physical therapy, dieting, or drugs are considered. Insomnia must be remedied, and carbomel (homodimethylacetoluen) in 5 to 15 grain doses is recommended. The essential in dieting is to avoid salads and coarse foods containing fibre, skins, seeds, or gristle, sweets should be limited. A short course of careful feeding is of value, since its failure will indicate that there is something organically wrong. With the exception of calomel and peppermint, most drugs are considered of doubtful value in the treatment of nervous indigestion.

### 344 Plasmochin in Malaria

B G VAD and G B MOBILE (*Indian Med Gazette*, August, 1927, p 430) have performed a series of investigations on the treatment of malaria by plasmochin, an alkylamino methoxy quinoline salt obtained by synthetic methods. It is a tasteless, light yellow, finely granular powder, fairly easily dissolved by alcohol, and soluble in water to a concentration of 0.03 per cent at 20°C, and rapidly converted into the hydrochloride by the hydrochloric acid of the stomach. In malignant tertian infections striking results were obtained. It was found that the drug began to act within twenty-four hours, the malarial parasites immediately disappeared, and in five or six days the blood was free. The temperature also was generally reduced within one day. The authors believe that plasmochin completely sterilizes the blood of malarial infection and controls the temperature within twenty-four to forty-eight hours, and that the results are both immediate and lasting. Other advantages are that it is administered orally, has no unpleasant taste or odour, and no untoward sequelae occur. An occasional and temporary rise of temperature after twenty-four hours is due to the fact that the drug begins to act at once, and the destruction of plasmodia is so great that the dead parasites, acting as foreign proteins in the blood, bring on a rigor with a rise in temperature. Vad and Mobile believe that plasmochin will supplant quinine and be effective in the treatment and prevention of malaria.

### 345 Treatment of General Paralysis of the Insane

J TUNEL (*Journ de Med et de Chir*, August 10th, 1927, p 546) discusses the treatment of general paralysis and states that while good results have followed prolonged and progressive injections of arsenobenzol and mercuric cyanide, remarkable benefit may be obtained by adjuvant treatment with sodium nucleinate and tuberculin. Intradural injections of mercurial salts or of arsenobenzol have been disappointing, but greater success has attended the intradural injection of salvarsanized serum. Combined bismuth and arsenical treatment has also been very effective. Tunel regards the introduction of pentavalent arsenicals such as stovarsol and trioparsol, and of the malaria treatment, as the most valuable advance made, but trypanamide has proved disappointing. He recommends the daily intravenous administration of 0.5 to 1.5 gram doses of stovarsol, commencing with the smaller dose and rapidly increasing it for fifteen to twenty days until a total quantity of 20 or 22 grams has been given. After an interval of a month, the treatment is repeated, similar doses being given. Hypodermic or intramuscular injections are said to be less efficacious. It may be necessary to give several courses of injections. Usually tolerance is perfect, but there is a danger of arsenical neuritis, especially of optic neuritis, producing partial or total blindness very rapidly, statistics suggest that this occurs in 8 per cent of patients undergoing this treatment. With this procedure 33 per cent of patients showed considerable improvement, though the Wassermann reaction does not become negative in the cerebrospinal fluid—normal in other respects, the blood reaction frequently becomes negative. Tunel finds that arsenical, mercurial, and bismuth treatments do not give permanent results, and their administration must be repeated constantly, few patients can endure suspension of treatment for three or four months without recurrence of symptoms. He recommends that intensive arsenical treatment should be alternated with bismuth or mercurial treatment. A daily quantity of half to one gram of stovarsol or trioparsol may be given by the mouth.

an alternate days with good results, although it may be a chemical dermatitis or severe diarrhoea. In optic neuritis has never been recorded. In fact, it is the only treatment for elderly or debilitated patients, particularly those suffering from tuberculous meningitis or cerebral disease. He recommends a short course of specific treatment before or after the injection of miltoid blood.

### 3-6. Haemostatic Action of Sodium Citrate

I GOTT and I PHILLIPS (*Brit. J. Surg.*, Aug. 20, 1927, p. 137) have confirmed the observations of various authors that sodium citrate has a strong haemostatic action and may be safely employed in cases of haematemesis, melena, haemoptysis and metrorrhagia. They injected intravenously 3 to 6 grams of a 50 per cent solution. They find that immediately after the injection the number of the leucocytes in the peripheral blood is diminished, they are no longer provoked but are collected in the spleen and liver. Fifteen to twenty minutes later these elements in the peripheral blood are increased beyond the figure observed before the injection. The number in the internal organs is diminished. These observations were made on rabbits. In human subjects there was a similar initial fall and later rise in the number of the leucocytes due not to destruction but to altered distribution. It was also that immediately after the injection the coagulability of the blood was diminished but fifteen minutes later it was increased a phase which lasted for twenty-four hours. The bleeding time was unaltered but the bleeding had an arrhythmic character. They regard these results as symptoms of shock following an altered colloidal equilibrium produced by the sudden introduction of sodium citrate into the blood. The mechanism by which the sodium citrate causes haemostasis is believed to be very complex, but is facilitated at the periphery by vasoconstriction and in the splenic area by the recombination of thrombocytes and leucocytes, which in mass are able to accelerate haemostasis.

## Disease in Childhood

### 3-7. The Heart in Early Life

S C SMITH (*Med. Jour. and Hosp.*, July 6th, 1927, p. 23) thinks that the heart in childhood is more easily damaged, it is also more amenable to treatment than at any other period of life. The right auricle and ventricle are normally enlarged during the first few weeks after birth in order to meet the demands of the pulmonary circulation. Slight digestive disturbances in children cause occasional intermittency of the pulse and purratory (sings) arrhythmia is also very common. In the adult when playing actively this arrhythmia is part of the physiological picture of the so-called adolescent heart. It is peculiar when the cardiac development does not appear to keep pace with the general growth. Such physiological conditions must be distinguished from the abnormal heart signs of the acute infections of childhood. Acute rheumatism in the pre-fibric stage may cause slowing of the pulse rate by ten to twenty beats, this is due to delayed conduction, a low grade heart block. In the pre-clinical stage of acute rheumatism complete (transient) heart block may occur the pulse rate being reduced by one third or even one half for a few minutes. Diphtheria may produce sudden fatal heart block. This is certainly prevented by the early use of antitoxin. A scarlet fever seldom attacks the heart in the acute stage. Whooping cough causes temporary dilatation of the right auricle but the author has never seen any conclusive evidence that whooping cough produces permanent abnormalities. Focal infections especially tonsillar and dental are now recognized as potent factors in rheumatic heart lesions, although periapical dental infections are far more rare than tonsillar infections in childhood. Falcidiosis tonsillectomy may prevent serious cardiac lesions. The author concludes that in a child any heart which exhibits a murmur however apparently innocent, should be thoroughly examined periodically in order to detect other possible evidences of later heart involvement.

### 3-8. Purulent Pericarditis in Childhood.

E G WILLIAMSON (*Annals of Surgery*, May 1927, p. 659) thinks that purulent pericarditis is fairly common in children. In 365 cases of pericarditis at Harvard 6 were purulent, and the author has collected from the literature 117 cases of which he has seen 18. In children 50 per cent were cured and discharged from hospital. Williamson states that the infection may reach the pericardium by direct extension of infection or through the blood, in most cases it is secondary to infection elsewhere. The pneumococcus is the organism most frequently found. Purulent pericarditis is diagnosed by the history and recent infection. When the effusion

is moderate palpitation, dyspnoea and quickening of the rate of respiration do not occur. As the effusion increases, emphysema and rapid heart beat become pronounced. X-rays give it resistance in diagnosis, and the physical signs are those of pericarditis with effusion. Liquefactive may be used both for diagnosis and treatment. Two drainage punctures of the sac and one of infecting the pleura. The site of puncture should be in the fifth interspace. Treatment is by incision and drainage. It is said to be wisest to remove one or more costal cartilages. The advantage of a drainage tube is doubtful in most reported cases it was not used and drainage was obtained by suturing the edges of the incised pericardium to the skin opening. Drainage has been used in some cases with decided benefit. It is likely that in all the cases the myocardium is markedly diseased as shown by signs of cardiac failure, energetic medical treatment is also required.

### 3-9. Swollen Breast in the Newly Born

C L ABT (*La Presse Méd.*, May 1st 1927, p. 457) has examined the swollen breasts of 635 newborn children (10 premature births). In 63.64 per cent of the cases secretion was present in the first month, descending to 57.14 per cent in the second, 46.87 per cent in the third and 50.68 per cent in the fourth month. It was more common in the male than in the female, and usually started after the second day, never as late as the fifth month. Labris adds that beyond delaying the onset, prematurity does not affect the constitution of the colostrum. There was no relation between the swelling of the breast and the colostrum fluid and microscopically the colostrum of the child was similar to that of the mother.

### 3-10. Neo-natal Haemorrhage and the Maternal Diet

C L MOORE and J L BRODIE (*Amer. Jour. Dis. Child.*, July 1927, p. 53) report a case of severe post-partum haemorrhage in an 8 part who e previous deliveries had been normal. The mother's diet during pregnancy had been markedly deficient in vitamin B as also in vitamin C. The infant died on the fifth day with haematuria, jaundice and diarrhoea. The autopsy showed the pathological evidences of beriberi. The authors have repeatedly observed similar gross and microscopical changes in the litters of laboratory rats fed on a ration very limited in vitamin B though other wise adequate. They conclude therefore that the chief cause of haemorrhage in this infant was the deficiency in its mother's diet in respect of this vitamin. The treatment suggested in such cases is liberal puncture and the subcutaneous injection of blood 50 c.c. for each kilogram of body weight in a single dose.

## Obstetrics and Gynaecology.

### 3-11. Pituitary Extract in Labour

In their search for a more effective and safer method of administering pituitrin than by subcutaneous injection J HOFBAUER and J K HOERNER (*Amer. Jour. Obstet. and Gynecol.*, August 1927, p. 137) were influenced by the following considerations. Since the best results follow the repeated administration of small doses during a number of hours, they thought that the local application of the extract to some highly vascular mucous membrane might possibly permit its slow and steady absorption. Moreover, inasmuch as patients vary in their reaction to pituitary extract, the drug could be withdrawn from this membrane when desired and thus prevent further absorption. Oral administration was first tried but though this method was efficacious in stimulating uterine contractions in some cases, the results were not quite satisfactory. After a careful consideration of the discovery by Freund that definite changes occurred in the mucous membrane covering the tuberculum septi and inferior turbinate in two thirds of pregnant women of the pregnancy reaction in the interarytoid region of the larynx described by Hofbauer of Vienna's suggestion that some relationship existed between certain areas inside the nose and the female genital tract, of work in Vienna on the relief of labour pains and dysmenorrhoea by the local application of cocaine to the inferior turbinate and of the reports by Abel and others on the beneficial application of pituitary extract to the nose in diabetes insipidus, the authors decided to try the nasal route. After preliminary sensitization of the uterus by hypodermic castor oil and quinine pledgets of cotton soaked in pituitary extract (10 minims to each) were gently inserted between the septum and inferior turbinate and under the anterior edge of the latter. These were fitted closely against the absorbing surfaces and did not lie loosely in the nasal cavity. When the effects caused the pledgets were removed and fresh ones inserted. As the pledgets were always found

heavily coated with mucus, thus impeding the absorption of the drug and causing considerable irritation, a new plan was tried. A pledget soaked with 20 minims of the extract was inserted into one nostril only, and at the end of one or at most two hours was withdrawn and a fresh one applied to the opposite nostril for a similar time. While 26 cases, with 7 failures, were treated by the first method, only one failure resulted in 54 cases when the improved procedure was employed. All the children were born alive. The authors maintained that the nasal application of pituitary extract is efficient both for inducing and for accelerating labour, and that the possibility of withdrawing the drug as soon as the uterus passes into tetanic contraction renders this method the safest yet known.

### Cervical Caesarean Section

352 R. F. ALIX (Nederl. Tijdschr. v. Geneesk., July 23rd, 1927, p. 393) records his observations on 76 cases of cervical Caesarean section in which this operation was indicated for the following reasons: (1) Contracted pelvis, 40 cases, associated with uterine atony in one case, large size of the child, each in one case. (2) Placenta praevia, 17 cases, the position of the placenta was central in 11 and lateral in 6. (3) Eclampsia, 14 cases. In addition to these principal indications there were others—namely, transverse presentation due to the large size of the child's head and cervical myoma, a very large child which could not be born per vias naturales, absence of external os owing to a previous plastic operation, polycystic ovaries, and vesico vaginal fistula. Eight of the 76 mothers died, in 6 cases owing to eclampsia and in 2 cases from unknown causes. The mortality among 77 children was 6, 4 deaths being associated with eclampsia and 2 with placenta praevia. Finally craniotomy was performed in 10 cases. Pfannenstiel's method, the scar becomes invisible in course of time. No rupture of the peritoneum. Median incision or no danger of infection of the peritoneum. Severe haemorrhage in placenta praevia is almost excluded. Median incision of the cervix causes less haemorrhage than incision of any other part of the uterus. Owing to the very slight degree of injury to the uterine musculature a better scar results and usually disappears after a year, with the result that there is no danger of uterine rupture in a subsequent pregnancy. Since the operation can easily be carried out extraperitoneally the occurrence of adhesions is almost excluded.

### Treatment of Placenta Praevia

353 THE two main conclusions drawn by A. P. RAYOS and JULIO B. SAN (Gynecol. et Obstet., July, 1927, p. 15) with regard to the treatment of placenta praevia are that labour should not be hastened artificially, and that improvement both in maternal and foetal mortality will follow more general recourse to Caesarean section. They advise that patients with placenta praevia should be sent at once to hospital, and remark that since nine out of ten cases of haemorrhage during the last months of pregnancy are due to low placental insertion, it is advisable to abstain from vaginal examination before admission to hospital, and to make a clinical examination made to Hirschmann's figures based on 6,000 cases of 20 per cent mortality in then homes showed a mortality of 20 per cent from placenta praevia, 4.5 per cent from placenta praevia, 1.9 per cent from placenta praevia, and those treated in hospital had a mortality of 15 per cent from haemorrhage and 1.9 per cent from infection, and those treated in hospital had a mortality of 6 per cent (4 per cent from haemorrhage and 2 per cent from puerperal infection). Other treatments than Caesarean section are indicated in some cases of marginal or lateral insertion in early stages of pregnancy.

### Pathology.

#### The Blood in Typhoid Fever

354 J. H. HARRIS and M. MOREL (Ann. de Med., July, 1927, p. 189) controvert the classic view that typhoid fever is a disease characterized by leucopenia and mononucleosis. A series of exhaustive examinations was made of 36 patients suffering from various clinical varieties of this disease but without complications. The erythrocytes were practically never increased, and a more or less intense leucopenia existed, especially at the time of defervescence. No alteration in the size or form of these cells and no nucleated varieties were ever seen. The authors found that leucopenia was not the rule, being present in only 20 per cent of cases in the first ten days, 40 per cent in the second, and 23 per cent in the third, it was usual only in cases prolonged to the sixth and seventh decades. More frequently a normal or slightly increased leucocyte count was found, a leucocytosis at the beginning of the attack being a favourable prognostic sign. Other findings were a slight myelocytosis of 1 to 2 per cent, an initial diminution, followed by a progressive increase, in the lymphocytes, the small mononuclears being markedly increased—especially during the febrile period—the large mononuclears remaining normal. A polynucleosis, normal or increased at the commencement of the disease, which rapidly gave place to a sometimes extreme mononucleosis, and an initial disappearance of the eosinophils, which reappeared at defervescence. Chalmers and Morel found that a relation existed between the results of the blood culture and agglutination results with the positive formula and blood culture and agglutination results which characterize uncomplicated typhoid fever, on the disappearance of bacilli from the blood the agglutination reaction, which had now become positive, was accompanied by a mononucleosis, with a greater or less evolution in the agglutinating titre and no parallelism or proportion between the two.

### Pneumococcus Type I in Sputum and the Mouse Test

355 RUTH GILBERT and C. K. DAVENPORT (Journ. Lab. and Clin. Med., July, 1927, p. 944) report an unusual case of apparent failure of the mouse test for pneumococcus Type I. A specimen of pneumococcal sputum inoculated on Avery's medium gave good growth after seven hours' incubation, and when submitted to the precipitation test a faint reaction was detected at the end of half an hour in the tubes with Type I serum, no reaction being obtained in the tubes with Type II and III serums. Type I serum was administered to the patient, whose condition rapidly improved, and he made good recovery. A mouse which had been inoculated with same specimen of sputum died in forty-eight hours, but agglutination, precipitation, and cultural tests demonstrated the presence only of pneumococcus Type III. Examination of the blood agar plates made from the sputum and also from the Avery cultures showed colonies of pneumococci and of *Streptococcus viridans*, suspensions of the growth washed from these plates were agglutinated by Type I serum, both diluted and undiluted, and also by Type III pneumococcus serum. Another mouse was inoculated with another specimen of sputum, it died after forty-eight hours. Agglutination and precipitation tests made with the peritoneal fluid showed reaction only with Type III serum. Following the inoculation of Type III appeared on plates made from the heart blood and from the peritoneal fluid. Two mice, two were killed I c.c. of a twenty-four hours' broth culture of Type I pneumococcus from this case into two mice, one after two days, and within twenty-four hours, one after two days, that the Type I pneumococcus from this case was pathogenic for mice, but the virulence of the culture was low.

### Calcium and Phosphorus Metabolism in Experimental Rickets

356 T. SKAAR (Norsk Mag. f. Laegevidenskab, August, 1927, p. 66) produced rickets in puppies by administering a diet consisting of skimmed milk powder, 20 per cent, and oatmeal, 80 per cent. Two litters of puppies were used, in each of which one served as a control, for the studies on the calcium and phosphorus metabolism. At the beginning of the experiments the puppies in the first litter were seven weeks old and in the second litter eight weeks. The duration of the experiment was three to four weeks. It was found that the calcium and phosphorus content of the blood serum was lowered in the rickets animals. Calcium was decreased 45 per cent (down to 5.38 mg per 100 c.c. serum) and the phosphorus more than 50 per cent (down to 8.5 mg per 100 c.c. serum). Studies of the metabolism showed that there were two forms of the rickets process—namely, one in which the calcium metabolism was affected primarily and another where the phosphorus metabolism was the first to suffer. When cod liver oil was given to a rachitic animal the calcium and phosphorus content in the blood serum rose to the normal value, but when sodium phosphate was given, there was a rise in the amount of 0.1733 gram of phosphorus in the twenty-four hours, the morbid condition was greatly alleviated. The changes became more pronounced, and there was a rise in reduction of the calcium and phosphorus balance. One puppy was given 2 g. of calcium lactate in addition to the rickets diet. The animal died during the experimental period but until its death had not shown such pronounced clinical symptoms of rickets as the others or so much decrease in the calcium and phosphorus content of the serum.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

357 **Classification of Hypertension**  
 N. M. KATH (U. S. Heart Jour. Aug. 1927, p. 597) remarks that it is now recognized that hypertension is not a disease but a symptom of a renal disease. It may be present for many years without impairment of health. The appearance of the renal vessels furnishes a valuable aid to prognosis but in an individual case it is unwise to attempt to predict the length of life. Kath divides the cases into three groups—the mild or benign, the severe or malignant, and an intermediate or severe benign group. Such differentiation is said to be valuable in prognosis. Renal haemorrhage is a most important symptom of the malignant type. It may be present while renal function is adequate. In 14 cases of this type death occurred within from one to four months. This condition may exist even in childhood and may follow general arterio-sclerosis and benign hypertension. The author cites the case of a cashier, aged 45, who had suffered from hypertension for approximately four years. The malignant form had been present for six months but until the first three months of life he was in comparatively good health. Then came rapid cardiac renal and cerebral failure. The majority of cases of this severe type of hypertension occur between the ages of 30 and 40 or 60. Beyond 70 it is infrequent though general arterio-sclerosis is prevalent at that age. Papilloedema is a striking feature and is often out of proportion to the other renal changes. In 81 cases renal tests at the initial examination showed approximately normal values in 21, mild insufficiency in 40, moderate changes in 7, and severe insufficiency in 7 only. In 3 of the latter chronic passive congestion was added. The results suggest that renal changes are more significant and occur earlier than demonstrable renal insufficiency. Many of these patients do not die from failure of one vital organ but rather from simultaneous cerebral, cardiac, and renal failure. The gravity of this condition is shown by the fact that 90 per cent of these 81 patients died within fifty-one months. Only 5 lived two years or longer. The average length of life after the diagnosis was made was eight months. Kath concludes that while the etiology of hypertension is still obscure the facts suggest that its primary cause is interference with the vaso-motor system possibly as a result of the circulation of unknown toxins or attributable to some unknown sympathetic disturbance.

358 **Acute Yellow Atrophy of the Liver**  
 C. P. HOWARD (Canadian Med. Assoc. Jour. September 1927, p. 966) discusses the incidence and clinical diagnosis of acute yellow atrophy of the liver and reports seven cases—two in men and five in women. Two women were in the early stage of pregnancy and two other patients were syphilitic, one a man and one a woman but in the remaining three no cause was indicated for the hepatitis. The cases exemplified the frequency of a gastro-intestinal onset at times so severe as to suggest an acute abdomen. Howard states that the disease picture is first that of a severe catarrhal jaundice lasting from ten to twenty-one days and passes suddenly into a toxic stage with an increase in the gastro-intestinal symptoms or the development of severe nervous symptoms such as delirium, twitchings, and convulsions, or drowsiness and coma. The jaundice usually deepens and the liver rapidly decreases in size and falls away from the chest wall, so that the relative dullness suddenly seems to be diminished. The pulse rate becomes increased to 120 or 140 and there may be hypopycnic just before death. The series of cases did not support the belief that leucem and typhoid are invariably present in the urine as they were searched for on three occasions and only found twice. While the whole illness lasts from five to six weeks the toxic stage averages about a fortnight though in one very severe case it lasted only two days. All the patients died but Howard adds that the disease is not necessarily fatal. In the literature thirty cases of recovery having been reported in the literature. He advises that in prophylaxis chloroform anaesthesia should be avoided in pregnant women who are jaundiced should toxic symptoms arise after salvarsan. 0.6 gram of sodium thiosulphate in 20 c.c. of distilled water should be given intravenously on four successive days. When the condition has arisen treatment can only be symptomatic though the administration of plenty of water by the mouth and intravenous injection of 10 to 20 per cent glucose saline solution

supplemented by insulin have been recommended. The vomit may sometimes be controlled by bismuth, and if vomiting is present all this should be given, either by the mouth, intravenously or by the rectum. In subacute cases kaolin, intravenously, to aid the glycogenic content of the liver has been recommended by Univer, who also advocates in syphilitic treatment, including salvarsan, when indicated.

## 359 Agranulocytic Angina.

C. J. KASTLIN (Inner Jour. Med. Sci. June, 1927, p. 799), who records two cases with a review of forty three other cases in the literature, states that agranulocytic angina occurs at all ages and in both sexes but more commonly in females. It is manifested by sudden rise of temperature, sore throat, dysphagia, chills and malaise followed by severe toxemia and prostration. It usually occurs during good health or may follow various chronic conditions especially oral infection. The symptomatology is not constant. Stomatitis is always present. There may be regional adenopathy and enlargement of the liver and spleen. Jaundice is common, while petechial haemorrhages are rare. Neutrophil leucopenia with relative lymphocytosis is always present. The blood changes being the result of the primary action of an unknown etiological agent on the bone marrow. A slight ordinary anaemia is sometimes seen. Ulcerative processes involving the tonsils, gums, tongue, larynx and oesophagus are secondary to the blood changes due to decrease in the body's resistance to infection. A lack of the cellular response to inflammation is seen in the ulcers as well as the pneumonic process which usually is the cause of death. The disease however is not always fatal. On recovery the blood returns to normal and a second attack of the disease may occur. The diagnosis must be made from conditions produced by certain poisons—such as thorium, arsenic and benzol—which may produce leucopenia, leucocytosis and albinism, leucocytosis, and from cases of crisis with leucopenia.

## 360 Post diphtherial Chorea.

A. A. GARO (La Pediatría July 1st 1927, p. 725) records the case of a girl aged 4 who about three weeks after an attack of diphtheria developed right hemiplegia and aphasia with choreic movements in the right upper limb. The cerebrospinal fluid was normal and the Wassermann reaction negative. Under treatment with large doses of antitoxin the child improved in a little more than a month she regained power of speech with complete use of the right side and recovered from the chorea. Only four other cases of post diphtherial chorea have been reported—by Baginsky, Oulmont, Globus and Critchley respectively. In spite of the absence of a pathological examination Augarano has no doubt that the symptoms were due to action of the diphtheria toxin on the brain, involving particularly the basal ganglia and the upper centres of co-ordination and control in the cortex.

## Surgery.

### 361 Surgical Treatment of Trigeminal Neuralgia.

W. F. SUERMONT (Dtsch. Zeit. f. Chir., September 1927, p. 216) records the results of treatment in 57 cases of trigeminal neuralgia during the last twenty years at the surgical clinic. 27 of the patients were men and 30 women. The disease affected the right side in 42 cases and the left in 13 while in 2 it was bilateral. Five patients were between the ages of 20 and 30, 5 between 30 and 40, 11 between 40 and 50, 14 between 55 and 60, and 22 between 60 and 75. In 3 patients the symptoms were not sufficiently severe to require operation and another 2 showed the value of a regressive operation and another 2 showed the value of a regressive operation and another 2 showed the value of a regressive operation. Since thorough examination of the eyes and nasopharynx, since one was cured by having astigmatism treated by spectacles, and the other by removal of nasal polyp. Four patients were treated with x-rays and all had recurrences. 14 had peripheral injections of alcohol with recurrences in all but 2. 6 had injections in the Gasserian ganglion with 2 recoveries and 2 recurrences while in 2 the results were unknown. Extirpation of the nerve was performed in 18 cases with 13 recoveries—1 recovery and unknown results in 4. Section of the inferior maxillary nerve was performed in 3 cases with recurrences in each. Intracranial operations were performed in 35 cases section of the nerve root being employed in 5, and extirpation of the Gasserian ganglion in 31 with a mortality of 5.2 per cent. The results of root section were 2 recoveries among the 5 cases and

among the 29 surviving patients who underwent extirpation of the Gasserian ganglion 24 were permanently cured and in 5 no information was obtainable. Suermundt concludes that extirpation of the Gasserian ganglion offers much the best prospect of recovery in trigeminal neuralgia. In mild cases an operation should first be performed on the peripheral nerve. If another operation is required later, it says should first be tried, but, if this is unsuccessful, extirpation of the Gasserian ganglion should be performed, unless this operation is contraindicated by the patient's general condition, when injection of the ganglion with alcohol may produce a permanently good result.

### 362 Tumours of the Spermathecal Cord

Z. ROWITZ (*Arch Ital Urol*, August, 1927, p. 531), who reviews the literature and records three personal cases, adopts the following classification of tumours of the spermathecal cord: (1) Connective tissue tumours properly so called, such as lipoblastoma, fibroblastoma, and myxoblastoma. Of these the lipomata are by far the most frequent, being represented by 61 cases, 37 of which have been collected by Patel and Chaher. Next come fibromata (21 cases, of which 12 appear in the statistics of Patel and Chaher), while myxomata are the rarest, and it is doubtful if they appear in a pure form. (2) Sarcomata of various forms, 30 examples of this group are on record, 20 of which have been collected by Patel and Chaher. Fibrosarcoma are the commonest. There are only three cases on record of giant celled sarcoma and one each of cysto sarcoma and peripheral sarcoma. (3) Dermoid cysts (12 cases) and teratoma (2 cases). (4) Mixed sarcomatous tumours (15 cases). Myxomatous tissue is almost always present, sometimes associated with fibromatous (3 cases), lipomatous (2 cases), or chondromatous (1 case) tissue. (5) Spindle blastomata. This group is represented by 8 cases, including examples of leiomyoma, fibroleiomyoma, angioloma, and lymphangioma. (6) Epithelial tumours. Only three cases of this kind are on record—namely, a carcinoma of the remains of the Wolffian body (Tedenat and Vien) and an epithelioma of aberrant seminal vesicles (Pignatti). The present author states that tumours of the spermathecal cord constitute 90 per cent of all extra testicular scrotal tumours, and are much less frequent than testicular tumours, which form 5.8 per 1,000 of all malignant tumours in man, while, unlike the latter, a large percentage of these are benign growths. In Rowitz's first case, which occurred in a man aged 53, the tumour was mainly a lipoma with a few disseminated foci of myxomatous tissue. In the second case, which occurred in a man aged 52, the growth was a myxosarcoma, and the third case, in which there was no clinical history, was an example of fibrosarcoma.

### 363 Acute Osteomyelitis

A. E. NORDHOLT (*Vedn. Tidsskr. v. Geneskl.*, September 10th, 1927, p. 1093) states that 100 cases of acute osteomyelitis were seen in the surgical department of the Coolidge Hospital at Rotterdam during the period 1921-25. Out of 60 cases where the pus was examined *Staphylococcus aureus* was found in 51, *Staphylococcus albus* in 1, *Streptococcus* in 7, and Vincent's organisms in a case of osteomyelitis of the jaw. In 56 cases the portal of entry of infection was not discovered, in 14 it was a boil, in 6 an infected wound, in 4 acute infectious diseases—namely, scarlet fever in 2 cases and measles in 2 cases. In 2 cases of osteomyelitis of the lower jaw dental caries was responsible. In only one case were infected tonsils the portal of entry of infection. In 15 cases there was a previous history of trauma. The localization was as follows: tibia 34 cases, femur 25, humerus 8, lower jaw 6, ilium 4, radius 4, ulna, fibula, and calcaneum 3 each, frontal bone 2, metacarpal 2, no attack, upper jaw, clavicle, scapula, ischium, and pubis 1 each. In 9 cases the process was multiple, several bones being usually affected simultaneously. The ages of the patients ranged from 4 months to 31 years, 71 were males and 29 females. The mortality was 6.4 per cent.

### 364 Ligation of the Femoral Artery in Obliterative Endarteritis of the Leg

T. E. NEILL (*Annals of Surgery*, September, 1927, p. 425) advocates tying the femoral artery below the origin of the profunda femoris in the treatment of obliterative endarteritis, as originally suggested by Dean Lewis of the Johns Hopkins Hospital. Following the operation a good collateral circulation develops, and Neill reports a case in which no inconvenience followed this treatment, but the diseased leg improved in a remarkably short time. Healthy granulations developed in the affected area, the gangrene began to recede, and the foot appeared definitely healthier, when the patient died suddenly, apparently in consequence of pulmonary embolism.

766 B

## Therapeutics.

### 365 Calcium Parathyroid Therapy in Epilepsy

REVIEWING the literature on the calcium parathyroid treatment of epilepsy and its effect on ammonia regulation, J. MADSEN (*Acta Med Scand*, August 31st, 1927, p. 536) quotes the hypothesis of Bisgaard and his co-workers that the disturbance of metabolism in epilepsy (dysregulation ammonia) is more or less connected with a functional disturbance of the parathyroid glands, there are, they state, many points of clinical and physico-chemical resemblance in parathyroidectomized individuals, tetanics, and epileptics. Their experiments showed that the injection of parathyroid extract changed the curve of a dysregulator to that of an orthoregulator, in some cases the curves did not vary more than the normal, while the extracts of other organs, such as the kidney, liver, and suprarenal gland, did not produce any effect. As the inconstancy of some of the results might have been due to an insufficient amount of active hormone in the parathyroid extract Collip devised a special method of preparation and of standardization, using as a unit one hundredth of the amount of extract necessary to raise the blood calcium of a normal dog weighing 20 kg, 5 mg per cent in fifteen hours. Former extracts were administered subcutaneously, but as oral administration of the new extract also influences calcium metabolism this method is now followed. Madsen conducted a series of experiments on epileptics, the patients being kept on ordinary hospital diet, and the first cases receiving no other medication. Later, luminal was given, as the condition of epileptics is aggravated by the discontinuance of all drugs, and the eventual effect of the parathyroid extract proved to be unaffected by this measure. In the regulation investigation fractional excretion of the urine was performed, dysregulation showing itself as soon in these as in twenty-four hour specimens. The pH was determined colorimetrically by Michaelis's method and the NH<sub>4</sub> N by a modified Van Slyke's technique, the aeration time was extended to three or four hours, since half or three quarters of an hour was found insufficient to expel all the ammonia. The total nitrogen was determined by Kjeldahl's method. Discussing his results in five cases Madsen asserts that Collip's parathyroid extract has a regulating effect on the ammonia metabolism of epileptics, the extract by itself has this effect sometimes, while in other cases the addition of calcium is required. Calcium alone is not capable of rescuing dysregulation. Improvement in the patient's clinical condition during treatment was so often noted that the benefits can hardly be attributed to incidental circumstances. In three of the five cases there was a marked reduction in the number of attacks as well as an improvement in the psychic condition. Madsen believes that the effects of the extract afford no evidence of the existence of parathyroid insufficiency in epilepsy.

### 366 Air Injections in the Treatment of Tuberculous Peritonitis

T. LUCHERINI (*Il Polmone*, Sez. Prat., September 5th, 1927, p. 1281) reports nineteen cases of tuberculous peritonitis of the exudative type treated successfully by means of the injection of atmospheric air into the peritoneal cavity. In one case pleurisy and pericarditis were also present, and air was injected into the pericardium as well as into the peritoneum with good results, unfortunately this patient died later from tuberculous meningitis. The author states that the injections should not be given during the acute stage, but only when the temperature is nearly normal and the abdominal pain is not severe. The amount of air injected should be about half the amount of fluid withdrawn, since the air takes up more room and expands. Ordinary air is said to give quite as good results as oxygen or any of the other gases which have been tried. Of the nineteen patients all were clinically cured except two, one of these died some months later from meningitis and the other from peritonitis. No ill effects were noted after the injections in any of the cases. Lucherini thinks that the air probably acts by stimulating the abdominal circulation, producing hypoxaemia in the Bier treatment, and possibly as a sclerogenic stimulus.

### 367 Ephedrine in Urticaria

BEATRICE M. KESTEN (*Arch. Derm. and Syph.*, August, 1927, p. 189) reports the results of using ephedrine in the treatment of six patients with chronic urticaria. Each patient received an initial dose of 50 mg of ephedrine sulphate by the mouth in capsules or in a 3 per cent solution, and the doses were repeated at intervals of two to six hours. The administration was continued until the symptoms were relieved or there was no improvement. In some cases, after failure to respond to the initial dose, the amount of the salt was increased to as much as 120 mg every two hours until benefit resulted. The

766 □

further pain, thus obviating the necessity for a general anaesthetic. The author concludes that pudendal anaesthesia is indicated in numerous conditions unsuitable for a general anaesthetic, such as pulmonary tuberculosis and heart failure.

### 374 Utero-Parietal Fistula

ACCORDING to F. PATTI (*Riv d'Ostet e Ginecol Prat*, July, 1927, p. 289) utero-parietal fistulae are among the rarest abnormal sequels of Caesarean section. Usually they appear within a few days of operation, but they may not become established for some months or even years. Spontaneous closure is unusual, but has been reported as occurring during pregnancy, on the other hand, the fistula is rarely complicated by conditions threatening life, although focal thrombophlebitis and a case of rupture of the uterus at the lower end of the fistulous track have been reported. The production of the fistula is due to infection, and would seem to be specially favoured by inclusion of the mucosa in the uterine sutures. Diagnosis is not always easy, but may be facilitated by the patient's remarking during menstruation a blood stained discharge where the fistula opens on the surface of the abdomen. It is possible to bring about contact between probes introduced into the uterus through the cervix and into the fistula, the opening of which may need to be dilated by a laminaria tent. In treatment medical measures and external applications are often ineffective, and laparotomy is often required, followed as a rule by hysterectomy.

### 375 Diagnosis of Ovarian Tumours

P. BROCC (*La Gynecol*, July, 1927, p. 413) emphasizes the importance of diagnostic accuracy in dealing with ovarian tumours, which may be mistaken eitherwise for fibromata and treated wrongly by radiotherapy. He reports four cases of large cystic or solid ovarian neoplasms in which such a mistake was made. The first patient was a woman, aged 36, who had a tumour (without metrorrhagia) which was diagnosed as fibroma and irradiated on twenty-two occasions. Three years later symptoms of torsion or rupture of an ovarian cyst occurred, and recovery followed its removal, though the patient complained of artificial menopause, due to x-rays. Another woman, aged 47, was irradiated for six weeks for metrorrhagia. After temporary relief the pain and haemorrhage returned, accompanied by abdominal swelling. Laparotomy revealed a large right ovarian fibroma, adherent to the pouch of Douglas, and showing non-malignant degeneration. The third patient, aged 52, had fourteen ineffectual treatments for a nodular tumour extending almost to the umbilicus, this was subsequently shown to be a large right ovarian cyst. The fourth patient, aged 42, had had three months' electric treatment following a diagnosis of metritis, and then thirty-eight irradiations for "fibroma," but laparotomy eventually revealed an adherent left ovarian cyst. A second papillary mass was adherent in Douglas's pouch, and the right ovary was also cystic. Subtotal hysterectomy was followed by complete recovery. Brocc thinks that such diagnostic errors occur frequently, and he adds that careful clinical examination, combined with intrauterine injection of iodolol or the introduction of a leaden sound will assist accurate diagnosis. There is no evidence that irradiation produces malignant changes in a benign tumour, but in doubtful cases exploratory laparotomy is preferable to diagnostic irradiation, since the latter may involve serious delay. The artificial menopause produced by irradiation in young patients is also a serious matter.

## Pathology.

### 376 The Rapidity of the Flocculation Reaction as a Guide to Potency

G. RAMON (*C. R. Soc. de Biologie*, August 26th, 1927, p. 635) states that the more rapidly a diphtheria toxin or antitoxin flocculates with a standard antitoxic serum the higher is its antigenic power, but the rapidity with which an antitoxin flocculates with a given toxin is independent of its antitoxin content. For example, of three serums, each containing 250 units of antitoxin, one may flocculate in two hours, another in five hours, and the third not for eight hours. Ramon thinks that there may be some therapeutic advantage in using a serum which shows rapid flocculation in preference to one which contains the same number of antitoxin units and flocculates slowly. He supposes that the more rapidly the serum flocculates *in vitro*, the more rapidly will it combine with toxin *in vivo*. He therefore endeavoured to find out what is responsible for the production of rapidly flocculating serums. The nature of the toxin or antitoxin injected appears to bear no relation whatever to the flocculation rate of the resulting serum, on the other hand, the

horse used for injection appears to be of importance. Horses with an initial Schick negative reaction not only give rise, as a rule, to serums having a higher antitoxin content than horses with an initial Schick positive reaction, but the flocculation rate of their serums is higher. It would appear that, at the time when a horse acquires a natural immunity to the diphtheria bacillus and a tendency to become hyperimmunized experimentally, its tissue fluids develop likewise a special aptitude to combine rapidly with toxin. For the production, therefore, of serums with a high flocculation rate it is advisable to use horses with an initial Schick negative reaction.

### 377 The Effect on the Thyroid Function of Vitamin B Deficiency

G. PIGHINI (*Biochimica e Terapia Sperimentale*, July 31st, 1927, p. 249) has fed tadpoles on thyroid pulp obtained from pigeons in which beriberi had been induced by the exclusive diet of polished rice. The thyroid glands of five such pigeons were pounded up together and placed in an ice chest. At the same time thyroid glands were collected from normal pigeons and similarly treated. Undifferentiated tadpoles (*Rana esculenta*) of about 40 mm in length and weighing 0.75 to 0.80 gram were distributed in three vessels—six to each—and nourished in pond water and spleen pulp. In the first vessel (controls) the hind limbs were developed by the eleventh day, but none of the tadpoles showed any signs of fore limbs. To the second vessel some thyroid pulp from beriberi pigeons was added daily to the diet, and by the eleventh day all had developed hind limbs but none showed fore limbs. To the third vessel thyroid pulp from normal pigeons was added daily to the diet, by the eighth day all the tadpoles had well developed hind limbs, and by the eleventh day they all showed commencing development of the fore limbs with shortening of the tails. These results show that thyroid pulp from beriberi pigeons is quite without effect on the metamorphosis of tadpoles, whereas the thyroid pulp of normal pigeons provokes marked acceleration in the metamorphosis. Confirmation is thus afforded of the observations that the thyroid gland of pigeons suffering from vitamin B deficiency has more or less lost its labile morphogenetic functions.

### 378 Pathogenicity of *Trichocephalus dispar*

ACCORDING to M. FERNÁN NÚÑEZ (*Arch. Int. Med.*, July 15th, 1927, p. 46) the pathogenic possibilities of *Trichocephalus dispar* have been insufficiently studied, the pathological lesions caused are thought to be more severe and important than has been generally recognized. The parasite is geographically widely distributed, and by experiment it has been shown that subcutaneous injection of the eggs into puppies produces infestation of the intestinal tract and that ova appear in the faeces. The author considers the parasite a definite cause of appendicitis, and that cases of idiopathic peritonitis occurring in tropical countries may be due to it. The tendency of the parasite to perforate the intestinal results in peritonitis, septicæmia, and pychitis. Pupa hæmorrhagia can result from this infestation and also pernicious anaemia, uricæmia, and goitre. By using a modification of Teichman's test Fernán Núñez found that the pigmentation in the intestinal mucosa of these worms was due to ingested human blood. He states that in those infested with this parasite eosinophilia is more constant and of greater severity than in any other nematode infestation, and indicates that the degree of toxin formation is considerable. In the tropics *Trichocephalus dispar* is associated in 33 per cent of patients with hookworm disease, and therefore treatment must be twofold lest the conditions produced by one be mistaken for those of the other. The author thinks it possible that this coexistence with hookworm has caused the harmfulness of *Trichocephalus dispar* invasions to be underrated.

### 379 Soy Bean Seeds as Culture Medium

L. VITALE (*Rassegna int. di elm. e ter.*, August 31st, 1927, p. 474) has found that a decoction of soy bean seeds with out the addition of peptone serves excellently for the preparation of solid and liquid culture media, forming a clear though not perfectly transparent broth of a pale yellow colour. Various substances may be added, such as lactose, agar, or gelatin, for the preparation of differentiating media, or for the cultivation of organisms for which the usual media are unsuitable. Organisms which grow on ordinary media grow equally well on a medium of soy bean seeds, and retain their morphological, cultural, and biological properties for a long period. Vitale suggests that the introduction of the soy bean seeds into bacteriological laboratories would effect a considerable saving in expense, since the bean costs little and 830 grams of broth can be made from only 120 grams of the seeds, which can afterwards be used for feeding the laboratory animals.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine.

250. Immunization against Scarlat Fever and Diphtheria

**Diphtheria**

11 L. F. D. J. 1937, p. 501. In a letter of 27th 1937, p. 501, advocates Laro's method of the only in certain towns with a percentage of sodium chloride. Such a soap can give local resistance but for all conditions contains no detergent and makes it possible to remove it from the throat and the skin with the same common white. The common sodium chloride used during the past twelve months (1937) was a 3 per cent solution of sodium chloride containing 100 mill on a level for a replacement and their towns and 61 L. F. D. J. in a town to each cubic centimetre. 1 cc of this solution is given sublingually or in the throat and repeated at weekly intervals for three days. In Minneapolis where 10,000 school children were so protected, statistics over a six month period show that the incidence of scarlet fever among the unvaccinated was 1 in 3,400, among the vaccinated was only 1 in 500. Of the 600 cases of diphtheria during the same period only 3 occurred among the vaccinated children.

351 D. E. McDermott (ibid., p. 560) reports the results of two series of scarlatinazations in Minnesota. In the first series of 54 Dick positive children were each given one dose of Larson's sodium ricinoleate scarlet fever vaccine which is equivalent to a 6000-unit test dose. Only in one case was there a local reaction which consisted of a scarlatiniform rash which lasted for about four hours. There was no local reaction in 29 cases and in the other patients it ranged from a small red spot to an area of redness larger than a silver dollar with or without some local induration. Subsequent Dick tests showed that 25 of these children were negative, 14 on 1 or 2 months and 23 were found still to retain their acquired immunity. In the second series 1931 persons aged from 1 month to 75 years—the average being 20 years—were each given three injections at intervals of one week of Larson's diphtheria and scarlet fever vaccine combined. All the reactions were negligible. The author adds that in the insular case concerned scarlet fever had been a very common disease and diphtheria in endemic or epidemic form almost constantly present for the past thirty years. He says, finally, that inoculations there had not been a single case of either disease for six months.

## Letar Pneumonia

L. L. ECHL, H. S. BALDVI and V. P. LARSEN (Arch Int Med September 15th 1927 p 253) record a clinical and bacteriological study of 2600 cases of lobar pneumonia the differentiation into the four types accepted by the Rockefeller Institute being based upon the capacity of the pneumococci to produce specific agglutinins, precipitins and protective bodies. An exact knowledge of the bacterial nature of the infection is considered to be indispensable in treatment and prognosis. A biological classification showed the following percentage of pathogenic organisms: pneumococcus 55.65, haemolytic streptococcus 3.8, Friedländer's bacillus 0.4, influenza bacillus 0.05 and *Staphylococcus aureus* 0.1. Young people appeared to be particularly prone to Type I infections, while elderly people were more liable to Type III. Considerable variation from year to year was noted in the incidence of the various types but the present series showed the incidence to be 33.6 per cent for Type I, 19.2 per cent for Type II, 13.4 per cent for Type III and 33.1 per cent for Type IV. In mixed infections the commonest variety was the association of the pneumococcus with the influenza bacillus, followed in order of frequency by a combination of the pneumococcus and a haemolytic streptococcus. No relation was found to exist between the type of pneumococcus and the lobe involved or the extent of the infection and no differences in the clinical course characterized the various types. 24 per cent of the pneumococcal cases showed the organism in the blood. Termination by crisis occurred most frequently in Type I infections, and Types II and III were the more severe forms. Age was found to be the most important single factor in determining fatality: pneumococcus Type I pneumonia having the lowest death rate presumably because it is the pneumonia of young people, while Type III pneumonia showed a high death rate chiefly because of its prevalence in old age. The relation of bacteremia to the death rate was striking, being 83.1 per cent where blood cultures were positive, and only 18.7 per cent in patients

who a blood remained sterile. Empyema was the most common complication occurring in 51 per cent of all cases. It is found to be much more serious when it developed during the active stage than when it occurred after the crisis, it is most frequent in typhoid infections.

## 283. A Recent Influenza Outbreak in Czechoslovakia

233. A Recent Influenza Outbreak in Czechoslovakia  
H. KRIKORIAN [Jr.] *et al.* *Leibniz* September, 1927,  
p. 1741 reports the clinical and pathological aspects of 70 recent cases of epidemic influenza and of the simultaneous epidemic hiccup. The blood picture in influenza corresponded almost completely with that found in the epidemic of 1918; there was leucopenia with relative lymphocytosis and disappearance of the eosinophilic cells. Influenza complications were similar to those of 1918. Remarkable features were the great susceptibility and the severe course of the influenza in cardiac patients; tuberculous patients were seldom affected, and in them the disease was mild. Animal experiments indicated the presence of a filterable infective virus in the nasal and nasopharyngeal mucus of influenza patients. Typical symptoms of the disease such as fever and loss of weight might have been produced by inoculation of the virus into the brain or peritoneal cavity of a guinea pig; the animals generally recovered. The inoculation was most effective when applied to the mucous membrane of the conjunctiva, nose, and nasopharynx; the resulting disease was of extreme malignancy—of eight guinea pigs six died. In two out of thirty six guinea pigs inoculated with influenza filtrate cerebral symptoms set in; these were shown in the first stage of the disease by somnolence and immobility; in the second stage by hyperaesthesia and rigidity and in the third stage by immobility, atony and transitory monoparesis. The agent appeared to be filterable; it passed through the Chamberland E3 filter and did not render the rabbit's cornea immune against herpes virus. During the epidemic outbreak soon after many cases of this distressing hiccup occurred mostly in young people. Experiments in transmitting this disease to rabbits and guinea pigs failed.

## 381 Streptococcal Septicaemia with Primary Joint Lesions.

P LÉVON and P LILJE (Bull et M m Soc M d Hop de Paris July 28th 1927 p 12-3) state that though the frequency and gravity of articular manifestations of streptococcal infection are well known the following case is of interest in view of the primary character and multiplicity of the joint lesions, which in the absence of blood cultures would have caused the case to be mistaken for acute articular rheumatism. The patient was a man aged 39 who was taken ill with high fever and inflammation of the right shoulder and right elbow. The left knee, ankle and elbow subsequently became affected. Blood cultures showed a haemolytic streptococcus. Death occurred after about a fortnight's illness. This unusual form of streptococcus infection recalls a case, reported by A CAW and P OURLY, of fatal streptococcus septicæmia in which the veins were primarily involved.

## Surgery

## 395      Results of Gastric Resection for Cancer

M. PEPERSON (*Annals of Surgery* September, 1927, p. 321) records the results of forty years' experience in the treatment of cancer of the stomach. The total number of cases was 1150 including 361 of resection, 450 of gastro-entrostomy and 339 cases of exploratory laparotomy. Of the 361 resection cases 101 or 28 per cent died in connexion with the operation while the mortality for gastro-entrostomy was 23 per cent. The mortality after resection increased from 20 to 38 per cent in 1921-25; this is attributed to more extended operations. Of 200 surviving patients, 161 (80 per cent) died within five years while 18 have survived for seven to twenty years after their operations. Scirrhus tumours have shown a greater tendency to relapse than other types of gastric cancer. Peperson thinks that the Billroth II and Polya operations have proved superior to the other types of operation. The employment of x-rays by improving diagnosis and technique has tended to increase the number of successful operations. Many patients have had their existence prolonged by a few years of good health after gastric resection but this form of treatment is still thought to be far from ideal.

### 385 Prevention of Pulmonary Complications in Gastric Surgery

X DELOPE and P JOUVE (*Rev de Chir*, No 5, 1927, p 355) draw attention to the frequency of pulmonary complications after operations on the stomach. The anaesthetic has for a long time been considered to be the chief offender, and it is true that it may tend to pave the way for pneumonia in those patients in a low state of health. But, in addition, it has been found that the same organism may be present in the stomach and the lung, and this suggested the employment of vaccine treatment, which has given excellent results. The vaccine contains pneumococci, staphylococci, enterococci, and *Bacillus tetragenus*. Injections are given on five days prior to operation. In 24 cases good results were obtained, 10 cases of gastric ulcer presented no pulmonary complications after operation, 3 out of 13 patients with gastric cancer died, but only one from chest complications, and this patient was in a very bad condition before operation. The remaining patient, who had pyloric intubation and spasm, recovered without any adverse incident due to the operation. The authors emphasize the importance of gastric lavage before and after operation, and consider the combined method well worth a trial.

### 387 Surgical Treatment of Constipation

M CHARBONNEL (*Journ de Med de Bordeaux*, September 10th, 1927, p 651), discussing surgical procedures for the relief of constipation, maintains that in young patients operating is inadvisable unless there is a strong likelihood of the presence of chronic appendicitis. In such a case the operation should be followed by medical treatment. If during the operation the appendix is found to be healthy it should, nevertheless, be removed, since small and invisible lesions imbedded therein may be the cause of the whole syndrome. Adhesions should be broken down, but, in general, if there is only an atonic dilated cecocolon no local operative measures should be attempted. The operation of Duval-Gregoire is said to be permissible in cases of ptosis and dilatation of the entire large intestine. In chronic cases, on the other hand, if there is more than thirty-six hours retardation, and if medical treatment has proved useless, it is better to perform a right colectomy without waiting for more severe trouble such as a perforating appendix. Charbonnel considers total colectomy a very grave operation, and only justifiable in a few cases of entire megacolon with total stasis. In cases of the functional type—that is, when the right iliac syndrome is only a part of the patient's troubles—he believes that no operation should be performed.

### 388 Cranial Changes in Neurofibromatosis

A WINKELBAUER (*Dent. et Chir*, September, 1927, p 230), who records an illustrative case with a review of the literature, states that in cases of von Recklinghausen's disease accompanied by facial lesions resembling elephantiasis definite bony changes are found in the cranium. The commonest changes comprise well marked asymmetry, thinning and narrowing of the bones, defective development, and deficiency of calcium salts. Less frequently hypotrophy and increased deposit of lime salts are found. It is not only the anterior parts of the facial skeleton which are affected, but the changes also extend to the base and the posterior parts of the skull. One manifestation of this is the dilatation or diminution of the sella turcica. The hypophysis itself is not the cause of these changes, and the attribution of the enlargement of the sella turcica to glandular hypertrophy does not appear to be justified.

## Therapeutics.

### 389 Synthalin in the Treatment of Diabetes

F RATHERY (*Paris Med*, September 24th, 1927, p 217) criticizes the indications and contraindications for the use of the synthetic product known as synthalin in diabetes enumerated by the German investigators Mosler and Foucresen, who stated that indications for its use were slight diabetes, in which the drug causes an increased assimilation of carbohydrates, in the diabetes of old subjects unable to become habituated to a restricted diet, in surgical or other complications which, in slightly glycosuric patients, cause an abrupt increase in the glycosuria and hinder cure, in simple diabetes becoming acidotic by hydrocarbon restriction and in severe diabetic cases in which glycosuric excretion exceeds the hydrocarbon ingestion—that is, fat diabetic patients with marked glycosuria. The drug was said to be contraindicated in severe juvenile diabetes with acidosis, in diabetes with cirrhosis and other hepatic lesions, in emaciated, asthenic diabetes with marked acidosis, and in diabetic coma. RATHERY thinks that the value of synthalin in diabetes has been greatly ex-

aggerated. Discussing its action in lowering hyperglycaemia, he states that this effect is neither marked nor constant, and Strass believes that it intensifies the hyperglycaemia. Many authors admit that the drug has a direct action on the liver, and from the dangerous symptoms produced experimentally in frogs and various animals RATHERY concludes that synthalin possesses a certain toxicity. It acts more slowly than insulin and is often badly tolerated, causing anorexia, vomiting, diarrhoea, sometimes oedema, icterus, and oliguria, and fats are badly assimilated. Anorexia is frequent, and the Germans claim that this is beneficial, since it diminishes polyphagia and facilitates restriction of the diet. In tuberculous diabetes this is rather a contraindication. The sensation of euphoria is not produced by synthalin as it is by insulin. In simple diabetes in whom the coefficient of assimilation is sufficiently raised to render them aglycosuric the use of synthalin, especially owing to its toxicity, is of no advantage. With patients suffering from tuberculosis and diabetes RATHERY has had favourable results from its administration, especially when combined with insulin, the benefit being greater than with insulin alone. He maintains that the use of synthalin is a matter for each individual case, and that it should be tried in subjects with insulin resistance, and in certain cases with the hope of diminishing the dose of insulin, that in the great majority of cases it can never replace insulin, and that it should never be given in diabetic coma. Another substance, glukhormon, obtained by von Noorden by fermentation of the pancreas, is similarly criticized by RATHERY as having no value in severe diabetes.

### 390 Potassium Permanganate in Small-pox

J H THEODORE (*Indian Med Gaz*, September, 1927, p 508) writes a preliminary note on the intravenous administration of potassium permanganate in small-pox. The external use of this drug for the prevention of pitting and scar formation is known, and Gordon has shown that a 1 in 100,000 solution destroys the vaccinia virus *in vitro*. Theodore set out to test the efficiency of the drug to destroy the viruses of vaccinia and variola *in vivo*, and to ascertain the value and the practicability of injecting a solution of potassium permanganate intravenously as a remedial measure in small-pox. The experiments showed that rabbits stood an injection, even repeated on three successive days, of 10 c.c. of a 1 in 500 solution of the drug without any ill effects. The author gave himself a similar dose and found that potassium permanganate did not affect either hepatic or renal efficiency. Further experiments indicated that the salt had a definite tendency to abort successful vaccination in rabbits. Finally, three patients with small-pox (the only ones available) were given single injections of a 1 in 500 solution. The results were eminently satisfactory, and the patients were discharged in sixteen, thirteen, and thirteen days respectively. Theodore states that potassium permanganate, administered to man in the strength and doses mentioned, exhibits no toxic properties, that the maximum dose tolerated is probably much higher than those tried, and that the results he obtained are sufficiently encouraging to warrant further trial.

### 391 Treatment of Rickets

J L GAMBLE (*Boston Med and Surg Journ*, September 8th, 1927, p 373) considers that the important practical result of recent studies of rickets is the rediscovery of the curative value of cod liver oil and sunlight. The administration of the former rapidly brings about an accurate restoration of the normal values for plasma calcium and phosphorus as does also sunlight, deficiency of sunlight and of a certain unidentified food substance which cod liver oil supplies are the chief causative factors in this disease. E T WIMAY (*ibid*, p 376) thinks that the need for anti-rachitic measures should be determined only after careful consideration of the adequacy of diet and the amount of sunshine received by the individual infant. He adds that severe rickets can be prevented with certainty in the majority of cases by giving cod liver oil, the mild form, only discoverable by x-ray examination of rapidly growing breast-fed infants, is probably physiological. In severe active rickets ultra violet irradiation in combination with cod liver oil assists matters, but artificially produced ultra violet rays are scarcely needed in prevention, since cod liver oil and sunshine are all that are necessary, the latter can be sufficiently obtained in winter by the use of quartz glass windows. J L MONSL (*ibid*, p 388) protests against the promiscuous use of ultra violet rays. He states that too prolonged irradiation of babies may inactivate the cholesterol in the skin and prevent it being reactivated by sunlight, by causing an excessive deposition of bone calcium it may also interfere with normal growth. He urges the need of a more thorough and scientific investigation before advocating the general use of ultra violet irradiation, since there is no justification for assuming that because it plays a valuable part in increasing the calcium content of the blood it will be of use in other directions also.

## 332. Calcium Chloride Injections in Pulmonary Tuberculosis

W. BROCKHANS (*Quart. Jour. Med.* July 1927 p 151) has given intravenous injections of calcium chloride to six patients suffering from pulmonary tuberculosis with such encouraging results as to satisfy him that this line of treatment is worth further investigation. The examination of seventy cases of pulmonary tuberculosis is shown that the serum calcium value was decreased when the disease was acute and increased when the patient recovered the difference amounting to as much as 20 per cent. It was not diminished by haemoptysis but individual cases varied so widely that it is not considered that estimation of the serum calcium is a trustworthy guide to the activity of the disease. Brockhans gave intravenous injections of 14 grams of calcium chloride three times a week and he adds that though the effect on the symptoms was good, in no case did tubercle bacilli rapidly disappear from the sputum. The most striking features were the gradual fall of temperature to the normal in patients who had failed to respond to absolute rest, there was progressive gain in weight and improvement in colour. In one case relapse followed discontinuance of the treatment and the injections had to be started again. It was found that when calcium was given by the mouth it failed to alter the serum calcium materially though intravenous injections raised it above the normal for forty-eight hours.

## Anaesthetics

## 333. Dichloroene Ether Narcosis

P. ALBRECHT (*Chir. Zeits. f. Chir.* August 1927 p 505) states that since 1923 he has used a mixture of ether and dichloroene which he has found preferable to a mixture of chloroform and ether. The advantages of dichloroene are that it possesses great resistance to light, is not uremic and alkaline and does not burn. Comparatively small amounts are necessary for deep narcosis. It does no injury to the circulatory, respiratory or central nervous systems or the parenchymatous organs. The blood pressure remains unchanged. Muscular twitching, which may produce can be avoided by preliminary administration of morphine. The use of the liver function by the galactose test before and after narcosis shows that the function is not disturbed at all. With half the patients there is no stage of excitement and in some of the others it is of short duration and ill marked. Vomiting is unusual. Spasms of the glottis occurs in about 5 per cent. Muscular relaxation follows after about ten minutes. The quantity of dichloroene ether mixture used for anaesthesia is not more than an hour's duration amounts to 97 c.c.m. ether and 35 c.c.m. dichloroene. The addition of dichloroene effects a considerable saving in the quantity of ether used. Of the total number of cases in which the mixture was used the results were good in 94 per cent. In 5 per cent there was some difficulty, but not enough to interrupt the operation, and in 1 per cent there were more serious symptoms such as cessation of respiration and asphyxia but no death. The post-anaesthetic effects were much less unpleasant than after chloroform ether narcosis. In two-thirds of the cases there was no vomiting. The addition of dichloroene also caused a great decrease in the number of lung complications.

## 334. After effects of Novocain Adrenaline Lumbar Anaesthesia.

MARGOT FRANK (*Deut. Zeit. f. Chir.* May 1927 p 263) describes two cases in which paralysis of the lower limbs and incontinence of urine and faeces followed a few days after the removal of varicose veins under lumbar anaesthesia with novocain adrenaline solution. The first case which ended fatally on the sixth day after operation was an apparently healthy man aged 26. The necropsy showed general hypertrophy of the lymphatic tissue and swelling of the lumbar portion of the spinal cord with a small area of softening, numerous small haemorrhages into the pia mater and cord particularly the posterior horns and conus medullaris were visible. The second patient a woman was still incontinent a year later and could only walk a short distance unsupported. She was found to be hypersensitive to an intravenous injection of 1 in 20,000 adrenaline as compared with controls and it was also found that some decomposition had occurred in the adrenaline employed during the operation. The author adds that since Heimke and Löwen's experiments showed that spinal anaesthesia was effected by direct contact and diffusion of the drug into the spinal cord and not by the blood vessels the addition of adrenaline can have little value in lumbar anaesthesia. For this reason and because of the possibility of hypersensitivity and the instability and deleterious effects of decomposition products of adrenaline Frank considers that the use of adrenaline for this purpose is useless and unjustifiable.

## 335. Nitrous Oxide Oxygen Anaesthesia

J. A. HINDENK (*Trachstia and Analgesia* June, 1927, p 116) recommends the following process for producing expeditiously an effective anaesthesia comfortable to the patient. It allows time for the sufficient distribution of the anaesthetic whereby the anaesthesia can be readily arrested and maintained on an even plane—i.e., oxygen added at the right time and in proper amount—the symptoms appearing slowly and separately and easy of interpretation. Administration is commenced with nitrous oxide 93 per cent and oxygen 7 per cent in volume to supply breathing—approximately 3 gallons a minute—given through both nose and propped open mouth for one minute. Oxygen is then discontinued until the desired symptoms of anaesthesia appear—in about forty seconds in the majority of cases. Oxygen (7 per cent) is then again introduced and has the effect of arresting the anaesthesia on the established plane and usually maintaining it there throughout the average dental operation. The administration of oxygen from the beginning and during the first minute eliminates the sensation of suffocation, excitement is reduced to a minimum, and the symptoms, which develop slowly, are mild in comparison with those produced by a pure nitrous oxide induction.

## Obstetrics and Gynaecology.

336. Liver Extract in the Toxaemias of Pregnancy  
H. A. MILLER and D. B. MARTINEZ (*Amer. Journ. Obstet. and Gynecol.* August 1927 p 165) report a series of 50 cases of pregnancy toxemia 7 being eclamptic and 43 pre-eclamptic treated with liver extract prepared according to R. H. Major's method. This is practically free from histamine and produces no uterine contractions in virgin guinea pigs. Stouffer has found that liver extract alone does not cause uterine contractions. Major and others have shown that it has a depressor action and from their results the authors deduce that it can act as a detoxicant in the toxemia of pregnancy. The dose varied with the case. In active eclampsia the extract was given intravenously in 20 c.c.m. doses every fifteen to thirty minutes depending on the resulting fall in blood pressure and the state of coma. In mild or moderately severe cases intramuscular injections were used. Hot packs and hydragogue cathartics were not employed the extract being the only drug used in the treatment. No ill effects were noted and only one death occurred the patient being moribund when first seen. In the other cases the symptoms rapidly abated. Headaches, dizziness, spots before the eyes, epigastric pain, nervousness and coma disappeared in a few hours. The oedema of the extremities and face also vanished in a few days and did not return so long as adequate doses were given. The urinary output increased and there was a decrease and sometimes disappearance of the albumin. The authors found that patients with known or suspected pre-conceptional nephritis were only symptomatically improved but all other cases derived marked benefit. Convulsions did not occur in any treated pre-eclamptic cases. They add that eclamptic patients must be kept under constant supervision and the drug given in doses sufficient to neutralize the toxin present in the individual.

## 337. Pregnancy Anaemia.

S. A. MCSWINEY (*Indian Med. Gaz.* September 1927 p 487) records a study of 43 cases of anaemia of pregnancy for which no obvious cause such as malaria or haemorrhage, could be found. The disease seemingly is much more common in India than in England and Hindustan provided most of the cases. The maternal mortality was 34.83 per cent and the foetal 58.1. The anaemia was much more frequent in early pregnancies and there were five times as many patients under the age of 30 as over. As the incidence of twins was more than five times the usual multiple pregnancy must be considered as a possible predisposing cause. The spleen was palpable in 7 patients and the liver in 5. In extreme cases the anaemia was profound and abnormal erythrocytes were seen in the graver cases while the total leucocyte count showed no striking variations. Albumin was present in 21 cases and markedly so in 5. Oedema of the feet and puffiness of the face were common while a general puffiness of the whole body occurred in 14 cases. The patients were markedly prone to miscarriage and premenstrual labour. The labours were noticeably bloodless, and post partum haemorrhage was observed in only one case. The author suggests the following etiological theories: (1) The mother's regenerative power to counterbalance the normal destruction of the red cells is inadequate. (2) The destructive action of the chorion villi on the maternal erythrocytes is excessive and comparable with the destructive action of the syncytium in chorion carcinoma. (3) Concealed syphilis must be considered, the Wassermann reaction being positive in 40 per cent.

cent of the patients tested. McSwiny advocates the use of iron and arsenic, plenty of nourishing food, fresh air, and sunshine, and whole blood injections. Whole blood transfusion is deprecated as being very dangerous, and weekly intramuscular injections of 15 to 20 c.c. instead are recommended. Specific treatment should be given when the Wassermann reaction is positive. As delivery favours recovery, pregnancy should be terminated, advisedly by slow and gentle methods of induction. The patient should also be warned against another pregnancy.

398 MARGARET I. BALFOUR (*Indian Med. Gaz.*, p. 491), who has investigated the histories of 426 cases in various parts of India, states that over 50 per cent gave a history of sudden onset, usually between the fifth and seventh months, and in 6 cases a history of similar symptoms in a previous pregnancy. Pylexia was present in 83.3 per cent of the patients, and diarrhoea, vomiting, and sore tongue occurred in 30 to 40 per cent, the diarrhoeic cases being the most fatal. Weakness, always reported, was not so marked as would be expected. The pulse was invariably rapid. Some times the anaemia persisted after delivery, but the patients usually recovered in six months. The majority of the cases occurred during the second half of the year, owing possibly to the greater prevalence of diarrhoea during that season. The author adds that the pregnancy *per se*, puerperal sepsis, and the common causes of anaemia do not seem to be causative factors. An infective origin is being investigated, and, since all classes of society are affected, a nutritional origin is considered, on the supposition that some necessary element may be lacking from the diet. The theory that the disease is a toxæmia due to the products of conception is discussed, and points of resemblance to eclampsia noted. The indication that women leading sedentary lives while enjoying a good dietary are more liable to suffer from this condition than others supports the toxæmic theory.

### 399 Repeated Cervical Pregnancy

N. MASIERI (*Riv. d'Obstet. e Ginecol. Prat.*, September, 1927, p. 361) records the case of a woman, aged 21, in whom pregnancy occurred in the cervix uteri on two occasions, respectively four and seven months after marriage, a pre-existing purulent cervico-vaginitis had been present. On the first occasion, after fifty days' amenorrhoea, a threatened abortion, complicated by considerable haemorrhage and foul smelling discharge, was diagnosed, pain, however, was almost absent. At the operation removal of the infected ovum from the cervix was attended with considerable difficulty and abundant haemorrhage, the supracervical cavity of the corpus uteri was empty. The second cervical pregnancy became interrupted spontaneously after thirty-five days' amenorrhoea, the removal of the ovum was accompanied by alarming haemorrhage, and the very vascular decidua was 7 to 8 mm. thick. Masieri refers to twenty-four cases of cervical pregnancy, in six of which death occurred from haemorrhage, he is inclined to think that in cases of well developed cervical pregnancy with grave haemorrhage rapid laparotomy and hysterectomy offer the best prospect of saving the patient's life.

## Pathology.

### 400 Variability of the Absorptive Power of the Skin

F. SCHULTZ RHONHOFF (*Zentralbl. f. Gynäk.*, October 1st, 1927, p. 2522) has investigated the absorption power of the skin as regards iodine during menstruation, pregnancy, the puerperium, and the non-pregnant state. Fifteen grains of 25 per cent iodine ointment was spread, without rubbing, on the flexure aspect of the forearm over an area 4 by 2 inches, ten minutes later and thereafter at five minute intervals the saliva was tested for iodine and the time of its first appearance noted. The room temperature was kept uniform, the forearm was neither washed nor disinfected, and was immobilized during the experiment. The results showed wide individual differences in the time of absorption. The average rate was slowest in the puerperium (66.6 minutes), next in pregnancy (54.8 minutes), and shortest in the non-pregnant (48.8 minutes). To eliminate individual differences the author examined the same women first in pregnancy, then in the puerperium, and found an increased delay of fifteen to twenty minutes in the latter. Stillinger's results were obtained by examinations during menstruation the increased time being then from fifteen to twenty minutes. There is less difference between pregnant and non-pregnant women than between the pregnant and puerperal, or the menstruating and the non-menstruating. To determine whether the delay was due to an alteration of the skin functions or of those of the salivary glands the urine was tested for iodine, and similar

results were obtained, thus eliminating the action of the salivary glands. Other observers have reported an increase in the iodine content of the blood during menstruation, towards the end of pregnancy, and during the puerperium, this suggests that the action of the skin is part of a general activity throughout the body. To test this phenomenon the action of the skin was cut out by giving the iodine by the rectum, and, contrary to the previous experiments, no delay was found during menstruation, showing that the skin was responsible for the altered reaction during the period. It was suggested that this delay was due to the increased sebaceous secretion during menstruation and puerperium, the skin was therefore thoroughly cleansed of fat and it was found that while the absorption time was shortened the accustomed delay during menstruation took place, showing that the cause of the delay in absorption lay in the skin itself, and was influenced in some way by the genital organs.

### 401

#### The Etiology of Typhus

P. HAUDUROY (*Arch. de l'Inst. Pasteur de Tunis*, September, 1927, p. 261) recalls the two radically different views of the etiology of typhus. According to some this disease is due to infection with *Rickettsia prowazekii*—a small organism which has been found in infected lice and in the tissues of patients and guinea pigs infected with typhus. The other view, which rests largely on the evidence afforded by the Weil-Felix reaction, is that the infecting organism is a particular variety of *B. proteus*, generally known as X 19, the blood of infected patients agglutinates this organism and, moreover, guinea pigs rendered immune to typhus are able to withstand several lethal doses of *B. proteus*. Recently Mlle Fejgin has endeavoured to reconcile these two views, she puts forward the hypothesis, based on some experimental evidence, that the *Rickettsia* bodies are in reality filterable forms of *B. proteus* generated under the influence of the bacteriophage. Hauduroy has performed some experiments to test the truth of this hypothesis. Starting with an anti-*proteus* X 19 bacteriophage, he found that its action was almost specific to the X 19 strain, there was little, if any, lysis of the *B. proteus* vulgaris strains. If a *proteus* lysate was filtered through a Chamberland L 3 crucible and the filtrate was incubated, it remained clear for about twenty days, then a faint opalescence appeared and increased until eventually a normal culture of *B. proteus* was obtained. Microscopically Gram-negative granules were at first visible, these were replaced, as the turbidity of the fluid increased, by typical *proteus* bacilli. The injection of an anti-*proteus* X 19 bacteriophage was without effect. Eight guinea pigs were injected intra-peritoneally with 5 c.c. of the bacteriophage, they remained perfectly well. Forty-six days later they were injected with the typhus virus, all of them developed typical experimental typhus. The examination of the stools, whole blood, and serum of a number of typhus patients failed to reveal the presence of an anti-*proteus* bacteriophage. The author maintains that, although these results do not support Fejgin's hypothesis, they do not disprove it.

### 402

#### Haematology of the Puerperium

The results of blood examinations on a number of lactating women performed by L. KRAUL (*Wien. klin. Woch.*, August 18th, 1927, p. 1045) during the normal puerperium confirm those of previous workers and show that a leucocytosis of 10,000 is the rule. He also finds that the blood picture is altered during and immediately after suckling, the main features of the change being an increase in the total number of white cells, while there is a relative diminution in polymorphonuclear cells and an increase in the lymphocytes. Kraul ascribes this partly to redistribution of blood consequent on the intermittent hyperaemia of the mammae during the phases of lactation and partly to expulsion of accumulated white cells from the uterus induced by the contractions known to be associated with lactation. The haemoglobin content and colour index of the red cells were found to be unaltered, but the velocity of sedimentation was increased. Intracutaneous and subcutaneous injections of saline solution showed that absorption in the skin was accelerated during suckling. The sensitiveness of vascular nerves to injections of adrenaline as gauged by alterations in blood pressure was, however, diminished. Glycosuria, estimated by fermentation tests, was more readily induced by adrenaline injections after ingestion of glucose in puerperal women in whom lactation had not occurred (on account of stillbirth or for other reasons) than in those who were suckling. He also found that instead of its usual pulse acceleration atropine frequently produced a slowing in the pulse rate of puerperal women, particularly while lactation was in progress. For these reasons, and others, the author concludes that a vagotonic condition of the vegetative nervous system exists during the puerperium in general but particularly during suckling.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine

### 403. Tobacco Smoking and Gastric Disease.

C. W. BARNETT (*Boston Med. and Surg. Jour.*, September 2nd, 1927, p. 457) gives a brief review of evidence obtained during recent years chiefly in Germany, suggesting that tobacco smoking plays a part in the production of peptic ulcer, gastric neurosis and even carcinoma of the stomach. It is generally acknowledged that smoking increases gastric secretion but it is doubtful whether hypersecretion leads to hyperacidity. The author has examined the records of all peptic ulcer histories from 1913 to 1926 at the Peter Bent Brigham Hospital. In about 100 female cases, no history of tobacco was noted and the work was then confined to male cases. As controls 500 general male patients aged 20 to 60 years, were taken. It was found impossible to group the cases according to the amount of tobacco consumed. The statistical methods of bulk were used and the standard errors of the variations were calculated for comparison of the various groups. Tables are given for the control's duodenal ulcers, gastric ulcers and gastric neurosis, and from an examination of them Barnett concludes that there is no proof that smoking is of any importance in the etiology of peptic ulcer or gastric neurosis or has any effect upon the age incidence of gastric or duodenal ulcer.

### 404. Paratyphoid A Meningitis.

G. PANSINI (*Studia*, September 10th 1927, p. 356), who records an illustrative case, states that Caronni and Auricchio isolated the specific organisms from the cerebro-spinal fluid in 14 out of 15 cases of typhoid fever although there was no clinical evidence of meningeal involvement. They are therefore inclined to recommend that a bacteriological examination of the cerebro-spinal fluid should be made in every suspected case of typhoid fever. Their observations however have not been confirmed by other writers. The general opinion, with which Pansini agrees, is that the cerebro-spinal fluid in typhoid fever is usually sterile. The presence of the bacillus in the cerebro-spinal fluid must be regarded as a sign of involvement of the meninges in the typhoid infection. As a rule the bacillus is found at the height of the disease either alone or in association with various cocci or the tubercle bacillus. In Pansini's case which occurred in a girl, aged 4 admitted to hospital with signs of meningitis, lumbar puncture two days before death gave issue to a clear fluid under considerable tension. Cytological examination showed a prevalence of lymphocytes with a few polymorphonuclear cells. The fluid agglutinated *B. paratyphus A* in a 1 in 50 dilution and this organism was recovered from the fluid. The serum agglutination test was positive in 1 in 200. Death occurred after eighteen days illness there was no autopsy.

### 405. Cerebral Venous Haemorrhage in Children.

Z. I. SLOIM (*These de Paris*, 1927, No. 23) who records an illustrative case, states that apart from obstetric haemorrhage in the newborn cerebral haemorrhage is rare in children when it does occur it is usually of arterial origin and due to softening caused by arteritis. In some cases however, as Parrot and Hainzel have shown the haemorrhage is of venous origin and due to an infection though the cause cannot always be discovered. In some cases there is also a history of inherited syphilis. The symptoms are often indefinite and may be those of a cerebral tumour. As a rule the diagnosis is not made before the necropsy. The anatomical lesions are multiple haemorrhagic foci and endophlebitis and periphlebitis of a cerebral vein. Sloim's patient was a child aged 18 months whose illness started with rhino-pharyngitis followed by fever and signs of tracheo-bronchial catarrh. A month after the onset convulsions occurred which at first were generalized and then localized to the right arm and the right side of the face and were followed by vomiting. The Wassermann reaction was negative. Death occurred six weeks after the onset. The necropsy showed haemorrhages beneath the cortex in the Rolandic area and the occipital and temporal lobes.

### 406. Enteric Fever in Malaya.

W. FLETCHER (*Bull. Inst. Med. Research Kuala Lumpur*, No. 4, 1927) states that owing to the increase in number of positive Widal tests at the Institute for Medical Research at Kuala Lumpur a report was made to determine if enteric fevers were common in the Federated Malay States and

if they were becoming more prevalent. There were no epidemics and typhoid lesions were rarely found at autopsies. The carrier rate was less than 0.03 per cent, in contrast with a rate between 0.3 and 1 per cent in the United States. The probable reasons for the low incidence of the disease were the evenly distributed heavy rainfall, the excellent water supply of the towns, the scarcity of flies, the absence of large milk distributing companies and the presence of colloidal clay in the rivers. As the result of repeated Widal tests and examination of the excretion of suspected cases 182 cases of typhoid fever, 9 of paratyphoid A and 5 of paratyphoid B were diagnosed during the years 1925 and 1926. Enteric fever was commoner in the small collections of native houses known as kampongs in which the drinking water is obtained from a shallow well or river and less common in the towns where there are usually excellent public water supplies. The mortality among the cases diagnosed in the locality was 13 per cent.

### 407. Influenzal Pericarditis.

P. L. TAYLOR (*Journ. Amer. Med. Assoc.*, July 30th, 1927, p. 347) who records a sporadic case states that pericarditis complicating pneumonia and empyema was frequently reported during the epidemic of influenza of 1918-19 and 1920. In 300 necropsies of patients who died of influenza pneumonia Stone found pericarditis in 24 per cent usually secondary to suppuraemia the infecting organism being as a rule the pneumococcus or haemolytic streptococcus. In only a few cases such as that reported by Malloch and Rhea has the influenza bacillus been found. Taylor's case occurred in a boy aged 6 who died after two days illness with pneumonia, laryngitis and pericarditis. A pure culture of *B. influenzae* was obtained from the lungs and pericardial fluid.

## Surgery

### 408. Thyroid Adenomata.

L. DALTREBANDE and A. LEMOET (*Bruzelles Medical*, October 9th 1927, p. 1584) define three groups of adenomata of the thyroid gland—namely the non-toxic, the grave toxic and the benign toxic. In the first group are simple adenomas unaccompanied by hyperthyroidism or any definite clinical trouble. The authors however insist that medical supervision is necessary since these growths may acquire the power of hypersecretion and ultimately become toxic adenomas. Descriptions of the toxic adenomas follow, and a table is given showing the differential diagnosis between cases of toxic adenoma and exophthalmic goitre. Estimation of the basal metabolism establishes the diagnosis with certainty, since it is raised 15 to 50 per cent in the grave toxic adenomas and in exophthalmic goitre from 30 to 150 per cent. The authors define grave toxic adenoma as a malady characterized by agitation, loss of flesh, tachycardia, generally arrhythmic, with or without palpable thyroid nodules, and having a metabolism constantly about 30 to 40 per cent above normal. Benign toxic adenoma occurs in patients whose general condition is good, there is no characteristic agitation, but only moderate tachycardia without arrhythmia. There may be palpable thyroid nodules and the basal metabolism is usually about 22 per cent above the normal. As the thyroid tumour may be imperceptible the basal metabolism should be determined in patients presenting tachycardia with or without arrhythmia, loss of flesh and a state of agitation. An adenoma may exist in the absence of a palpable thyroid lesion. In both palpable and non palpable cases the treatment required is subtotal thyroidectomy.

### 409. Anal and Rectal Polyp.

BELIEVING that anal and rectal polyps should be classified as precancerous growths B. H. BEELER (*Amer. Journ. of Surg.*, August 1927, p. 142) reports four cases of carcinoma of the rectum in which the histories plainly revealed its origin from benign polypoid growths. One patient had noticed for nine years a small lump prolapsing with each stool, a second patient had noticed two small hard tumours prolapsing with each defaecation for fourteen years, in the third patient a small, hard tumour had propped at each stool for some years while the fourth patient reported that on some time previous to an operation she had been troubled with the prolapse of a small tumour at each stool. On rectal examination a hard indurated growth was felt in all the patients,

and the microscopical diagnosis of each tumour was a leucocarcinoma. Two of the patients were treated, apparently successfully, by electrocoagulation. In the third case, merely to control haemorrhage, the whole area was sutured with catgut. This contracted the mass to half its size, and controlled the bleeding. The patient has improved, and the growth appears to have been arrested by a very simple procedure. The fourth patient, refusing colostomy, received radium treatment, but died in a few months of carcinoma. Beeler maintains that cancer of the rectum is very frequently the result of long standing polypoid growths, that diarrhoeas and mucous colitis call for very careful examinations, and that all rectal complaints should be investigated digitally at least. He states that electrocoagulation offers a very good method of treating cancers situated posteriorly in the ampulla and within reach of the finger, its success depends upon the stage of the growth. In the first stage of development cure is possible, in the second, only arrest of the growth and control of haemorrhage and pain can be attained, while cancers in the third stage are inoperable, and cannot be cured by any known method.

#### 410 Lithotripsy

M. PAVONE (*Journ. d'Urol.*, September, 1927, p. 193) recalls that the long practised operation of crushing a stone in the bladder underwent its chief modification when Bigelow introduced his evacuator. By this method the operation of crushing and removal of the fragments were completed at one sitting, and the mortality was much reduced. With regard to anaesthesia, some surgeons use chloroform to render the bladder insensible to the manipulations necessary and to avoid reflex contractions. Pavone prefers a local anaesthetic and employs cocaine combined with morphine, by this method the contractions of the bladder are utilized in the later stage to expel the fragments of the calculus. Spinal anaesthesia is said to be excellent for the crushing part, but it persists too long, and the bladder is paralysed also. Cystoscopy is combined with the operation to make certain that all the stone has been evacuated. Lithotomy is the operation of choice as a rule, and cystotomy should only be used in special cases where contraindications prevent the use of the lithotrite.

#### 411. Treatment of Spinal Fracture

S. W. BOORSTEIN (*Amer. Journ. of Surg.*, August, 1927, p. 116) gives statistics of sixty-one cases of spinal fracture treated between 1915 and 1925. He emphasizes the importance of excluding this condition in every case of apparent injury to the spine, immediate rest being enforced until the investigations are complete. A radiogram should be made as soon as possible, but if the indication is negative the radiological examination should be repeated in a few days, as the lesion may then be manifest. Boorstein recommends rest on a Bradford frame, followed by the application of a plaster jacket or of two plaster shells. If the cord is injured and there are positive signs of pressure laminectomy should be considered, and this may be advisable even if there are no such signs. In complete transverse paralysis it is doubtful whether an operation will help. Boorstein adds that in late cases where pain persists a fusion or bone graft operation for the spine should be considered.

## Therapeutics.

#### 412 Treatment of Epilepsy

R. N. SANTOS (*Arch. de med. cir. y esp.*, October 1st, 1927, p. 393) states that Ghitovich and V. K. Chorocho in 1925 introduced a treatment of epilepsy by cerebral emulsion and anti-rabic vaccine. Ghitovich used anti-rabic vaccine exclusively in fourteen cases, but the results were not uniform, as he obtained improvement in only a few, as shown by diminution in the number and severity of the attacks and an attenuation of the psychical symptoms. Chorocho employed an emulsion of a normal rabbit's brain and a 10 per cent rabies virus, and obtained more encouraging results, as there was a considerable diminution, and in some cases a complete disappearance of the attacks. The rationale of the treatment has not yet been exactly explained. It is unknown whether the cerebral emulsion acts as a foreign protein or if it has a specific action. Santos employed an emulsion of cerebral substance in a 20 per cent solution of luminal sodium. The nine patients selected, whose ages ranged from 14 to 32, were all subject to frequent epileptic attacks and in most of them the ordinary treatment had failed. In almost every case he obtained very marked improvement, which persisted after the injections had been discontinued. The usual dose was 2 cc. every other day until ten injections had been given.

#### 413 Action of Lobeline

ACCORDING TO J. MOUZON (*Presse Med.*, October 12th, 1927, p. 1239) the employment of lobelia should be reconsidered in view of the discovery of lobeline, which is obtained from *Lobelia inflata*, a plant well known in North America, during its flowering season, this alkaloid is crystallizable, and appears to have the empirical formula,  $C_{13}H_{21}O_2N$ . In concentrated solutions it forms a clear, yellow, oily liquid. The hydrochlorate is the salt generally used, and its injection, even subcutaneously, is painless. Eckstein, Wichard, and other experimenters state that this product is a very energetic stimulant of the respiratory centre. Injected intravenously in doses of 0.003 gram (about 1/20 grain) lobeline causes, in a few seconds, a very marked change in respiration, the inspirations becoming deeper and often more accelerated. This action is very transitory and lasts only eight to ten minutes, when the drug is either eliminated or destroyed. Larger doses of 0.01 gram (about 1/6 grain) are employed subcutaneously or intramuscularly, and by these methods the action of the drug is delayed, commencing in seven to eight minutes, and lasting for a longer period of about twenty minutes. Subarachnoid injections act as rapidly as intravenous ones, but the dose required is smaller and the action persists longer. Toxic doses paralyze the respiratory centre and produce convulsive symptoms. The intensity of this action has led to the trial of lobeline, especially in Germany, in the apnoeas of bulbar origin. Beneficial effects have resulted from its administration in the apnoea of the newborn, in respiratory failure in general anaesthesia, and in grave intoxications by narcotics. Before administering lobeline it is essential that the air passages be free, and all revulsive procedures eliminated. Dangers attend its use, due to its action on the heart, it excites the cardiac fibres of the pneumo-gastric nerve, diminishing the cardiac contractions, lowering arterial pressure, and loss of rhythm. Owing to this action, many have abandoned its use. Other ill effects have been noted, such as spasms of cough and vomiting. Mouzon thinks that these harmful sequelae may be due to impurities, since the preparation of the alkaloid is a difficult matter. Its antidote is atropine, and Wright and Curtis (see JOURNAL, 1926, vol. II, p. 1225) have recommended its combination with adrenalin or pituitin. In view of the dangers attending its use, and until further studies have been made concerning its action, Mouzon advises that the drug should be used only as a last resort in the conditions mentioned.

#### 414 Therapeutic Measures in Neurosyphilis

J. E. MOORE (*Journ. Amer. Med. Assoc.*, August 20th, 1927, p. 533) summarizes the results of treatment at the Johns Hopkins Hospital of 261 patients with different types of neurosyphilis. He insists that adequate treatment of early syphilis is all important, with the intelligent use of spinal fluid examinations early in the course of the infection. In early or late syphilis with slight spinal fluid changes, or in late syphilis with minor neurological signs and a negative spinal fluid, the routine treatment by injections of an arsenphenamine compound, alternating with courses of mercury or bismuth in large doses of potassium iodide by the mouth, is advocated, while early meningeal and late meningeal vascular cases require an intensified routine treatment by larger doses and longer courses. The author thinks that serologically resistant cases and cases of general paralysis should be treated with triarsenamide, with mercury or bismuth alone, or in combination with an arsenphenamine, or by malin therapy, in some cases, and particularly in optic atrophy, intraspinal treatment appears to offer the only chance of arresting the process. With such procedures it has been possible in an ambulatory clinic to obtain 62 per cent excellent or good combined clinical and serological results in early meningeal neurosyphilis, 59 per cent in late meningeal vascular, and 31 per cent in tabes. Remissions were produced in 57 per cent of a small series of patients with early general paralysis, and 40 per cent satisfactory results were obtained in early primary optic atrophy. Moore adds that treatment must always be individualized, and must often proceed on a system of trial and error.

#### 415 The Use of Mud Baths in Treatment

E. BARRAL (*Journ. de Med. de Lyon*, October, 1927, p. 489) describes the use of the radio-activo vegeto-mineral mud of natural hot springs in various resorts in France and on the Black Sea coast, where mud from the "Limans," or saline salt lakes, is warmed by exposure to the sun or by artificial means to a temperature higher on the average than that of the natural hot springs of France, treatment is augmented by bathing in the water of the "Limans," which contains a very high percentage of salts. The mud acts as a general or local cataplasma, and contact with it can be borne at higher temperatures than in the case of water. After a transient

vaso-constriction there is vaso-dilatation and a gradual rise of general body temperature, these persist, with perspiration and diuresis, for some time after the discontinuance of the bath, and disappear slowly. Respiratory movements become more rapid and shallow. The thermal action of mud is said to have a particularly beneficial effect on chronic rheumatic or inflammatory conditions of joints. Iodine emanations from the radio-active waters and gases are believed to further the elimination of uric acid. Contact with the mud stimulates the cutaneous circulation, and such volatile substances as ammonia and sulphuretted hydrogen are capable of absorption by the skin. Concentrated saline solutions produce a general erythema of the body surface. The changes in electrical potential due to immersion in mud baths are thought to benefit some chronic conditions. The author quotes Borisor's theory as to the action of mud baths—that in general, their effect is to convert chronic into acute conditions, thus increasing the efforts of the body to eliminate the harmful agent. Borisor considers that mud baths are contra-indicated in all acute and febrile conditions, particularly pulmonary tuberculosis, as also in degenerative conditions of the cardiac muscle and blood vessels. The special indications for treatment by mud baths are chronic rheumatoid conditions of the joints, surgical tuberculosis when not acute, persistent palatal inflammatory affections, such as chronic parametritis and tertiary syphilis.

## Neurology and Psychology.

### 416. Myopathy of the Adult.

DUCHENNE in 1861 described a new morbid entity which he termed pseudo-hypertrophic or myo-sclerotic paralysis of infancy, and several authors have brought to light the existence of a rarer form, pseudo-hypertrophic myopathy in adults. According to G. GUILLAIN and A. PÉRO (*Paris Med* October 1st, 1927 p. 239) the topography of the muscular hypertrophies and atrophies in adults and infants is very comparable. Pseudo-hypertrophy manifests a predilection for certain groups of muscles in the lower limbs the soleus, the gastrocnemius and tibialis anticus and in the upper the deltoid. Atrophy often associated with pseudo-hypertrophy involves the muscles at the attachment of the limbs, those of the scapular and pelvic girdles being chiefly attacked, it progresses from the proximal to the distal segment. As a general rule involvement of the small muscles of the hands and feet is very rare and appears only as an atrophy. The authors report a case which illustrates these points. In a man aged 37 the atrophy was very marked in the thoracic and abdominal muscles as well as in those of the scapular and pelvic girdles, the pseudo-hypertrophy involving the muscles of the hands and slightly those of the forearm, the solei, gastrocnemii, and the pedal and plantar muscles. All these lesions were symmetrical. The galvanic and myotonic reactions were markedly increased and showed an analogy between Duchenne's paralysis and Thomsen's disease. There were great variations in the tendon and bone reflexes while the cutaneous were normal. No sensory or sphincter troubles were present. Vasomotor disturbances were very marked in the extremities, the hands and feet being habitually cyanosed and the skin cold and constantly moist with an excessive sweating. The Wassermann reaction of the blood was negative. The heart was normal but the arterial pressure was relatively low. The patient was weakly, of feeble intellect and exhibited marked mental disturbance being obstinate and violent. The muscles showed the following characters: increase of volume, modification of consistency, diminution of muscular force despite the hypertrophy, absence of fibrillary contractions and myotonic reactions and the presence of vasomotor alterations. There were no hereditary antecedents. When 17 years old he had an attack of typhoid fever, and one of the authors insists that this infection plays a part in the production of certain acquired and non-familial myopathies. The authors emphasize the topography of the muscles affected, the association between the clinical and electrical examinations and the late onset of the disease. They add that acquired myopathy is more frequent in only one member of a family than is the familial type.

### 417. Aphasia due to Cerebral Tumour.

M. J. COHEN (*Journ Med Assoc S Africa* July 23rd 1927 p. 358) gives details of speech changes occurring in a case of tumour of the left temporo-sphenoidal lobe in a woman aged 49. She complained of headache, vomiting, nausea, severe, bilateral vision, general weakness, vomiting, nausea and defective memory which proved on examination to be more exactly an inability to use certain words. The head ache was confined to the left side and extended more towards the frontal than the occipital region. It occurred at first

mainly at night, and it was followed two months later by vomiting, of the cerebral type, with inability to use certain words, general asthenia, with fainting attacks, supervened. The patient's mother was said to have died of cerebral tumour and there was a history of an accident sixteen years ago when a fall from a cart rendered the patient unconscious. When first seen by Cohen there was no paralysis, and beyond a trace of sugar in the urine the organs were healthy. The Wassermann reactions of the blood and cerebro-spinal fluid were negative. Papilloedema of both discs more marked in the left than the right was present but there were no haemorrhages or white retinal patches until a month later and there was no hemianopia. The knee jerks were exaggerated, and there was no ankle or patellar clonus. She complained of dizziness on walking, but there was no weakness, ataxia, rigidity, or tremor. She could write down dictated words and repeat sentences, but could not express herself, being unable to find the words to use or name objects (nominal aphasia) and she repeated a name once spoken (perseveration), her condition being suggestive of a lesion involving the third left frontal convolution. She could carry on a conversation usually, but stopped repeatedly for want of a word, usually a noun, when this was repeated to her she would insert it in the right place. On trephining, a month later, no tumour was found but the brain bulged and the vessels of the dura were obliterated from prolonged pressure. There was no fluid in the ventricle but this was found later to be due to its being almost obliterated by the pressure of the growth. The persistence of speech anomalies (paraphasia, agrammatism, and verbiage) after decompression pointed to the portions affected being not so much pressed upon as infiltrated ideas being apparently well formed at the cortex but blocked in transmission owing to the destruction of association fibres by infiltrating growth. At the necropsy a tumour at the tip of the left temporo-sphenoidal lobe was found infiltrating the left third frontal convolution and stretching laterally as far as the left corpora quadrigemina and posteriorly almost to the cerebellum. Histologically it was a vascular gliosarcoma with areas of necrosis and haemorrhage. Cohen states that in cases of cerebral tumour the bone should not be replaced over decompressed areas especially where a large pulsating growth exists.

### 418. Etiology of Disseminated Sclerosis.

L. TOMMASO (*Il Policlinico Sez Med* September 1st 1927 p. 482) discusses the etiology of disseminated sclerosis with special reference to the possibility of its being comparable with syphilitic lesions and of its being treated effectively by malaria therapy. That there is an affinity between disseminated sclerosis and cerebro-spinal syphilis has been affirmed by Dufour and Ganchet, the negative view is held by a larger number of writers including Nonne, Pierre Marie and Sclard, who distinguish the diseases by clinical data and by their pathological anatomy, bacteriology, and serology. In 1917 the experiments of Kuhn and Steiner favoured the hypothesis of a specific infection in disseminated sclerosis, and cited *Spirochaeta argentinensis* an observation supported in 1921 by Siemerburg, who found the same spirochaete in the sclerotic plaques. The possibly spirochaetal nature of disseminated sclerosis has led some authors to treat patients by the induction of malaria. Of forty two cases so dealt with by Grosz a lasting improvement was recorded in eleven. Tommaso reports two cases in both of which the results of experimental inoculation with malaria was negative and he emphasizes the fact that spontaneous amelioration is common in this disease even when malaria treatment has not been employed. He concludes that the spirochaetal origin of disseminated sclerosis cannot, therefore, be accepted as established.

## Obstetrics and Gynaecology.

### Movements of the Ovary.

419. ACCORDING TO T. MICHALITZ (*Zentralbl f Gynäk*, September 17th 1927 p. 2394) the ovum in tubal pregnancy which usually has taken the normal path of entry into the Fallopian tube of the corresponding side may also in rarer instances have adopted either of the following courses: (1) through the abdominal ostium of the Fallopian tube of the other side to become embedded in that tube. (2) through the abdominal ostium of the Fallopian tube of the same side, thence through the uterus to end in nidation after entry through the isthmus tubae in the contralateral tube. To these abnormal courses the names 'external wandering' and 'internal wandering' may be given respectively but it has been denied that the ovum ever takes the second course. Evidence of the occurrence of 'external wandering' is based on the facts that (1) a considerable proportion of tubal gestations the ovum is found on the side opposite to the corpus luteum and

(2) the tube may be absent or occluded on the side corresponding to the corpus luteum, the ovary on the side of the tubal pregnancy containing no corpus luteum. "Internal wandering" of the ovum (into one tube from the other through the uterus) may be assumed to have occurred if the abdominal ostium of the gravid tube is certainly closed and the contralateral tube is pervious. Certain cases of double gestation in one tube, with ova of different ages, can be explained by "internal wandering" of the ovum. In Santer's case a two months' ovum was present in the outer third and a three to four weeks' ovum in the inner third of the same tube, on the corresponding side an old corpus luteum was present. The older ovum was thought to have come from the same, the younger from the opposite, side, nevertheless, the abdominal ostium of the gravid tube was open and the fimbriae were preserved, so that the possibility that the younger ovum had slipped past the older, traveling towards the uterus, cannot be denied. In a case described by Micholitsch the left tube contained in the ampulla a molar connected with a thick walled haematocoele, and at a distance of six centimetres an intact ovum in the uterine end, the ages of the ova were respectively two months at least, and three to four weeks. Since the abdominal ostium was completely filled by the molar and the fimbriae were intimately involved in the capsule of the haematocoele, the conclusion is drawn that the younger ovum could only have gained entry into the tube through the uterus. The right ovary contained a recent corpus luteum.

#### 420 Primary Tubal Cancer

C STANCA (*Gaz des Hop*, August 31st, 1927, p 1155), who records an illustrative case observed by him in the gynaecological clinic at Cluj in 1917, states that cancer of the Fallopian tube is a very rare condition. Barely 180 cases have been recorded, of which only 33 per cent are primary and the rest secondary. Primary tubal cancer arises from the mucous membrane of the Fallopian tube, and may become diffuse or circumscribed, while secondary cancer follows a growth in the uterus or ovary. Histologically tubal cancer has been divided by Singer and Baith into simple papillary carcinoma and alveolar carcinoma. Chronic salpingitis, due to puerperal fever, tuberculosis, and other causes, is regarded as predisposing to tubal cancer. There are no pathognomonic symptoms, and there is no case on record in which the diagnosis has been made before the operation or autopsy. The course of the disease is characterized by early and multiple metastases, which in most cases render surgical intervention of no avail. Only 4 per cent of the cases in which an operation has been performed have been radically cured. In inoperable cases encouraging results may be obtained by deep x-ray treatment. Stanca's case occurred in a multiparous woman, aged 40, who had suffered from general weakness and abdominal pain for seven months. A diagnosis of malignant growth of the adnexa was made and laparotomy performed, when a tumour of the left Fallopian tube and a right hydrosalpinx were found. Owing to haemorrhage and extensive adhesions bilateral removal of the uterine appendages with drainage of Douglas's pouch was performed. Death from peritonitis followed the operation. Histological examination of the growth showed that it was a papillary carcinoma.

#### 421 Retroposition of the Uterus after Labour

A FRUHNHOLZ (*Bull Soc d'Obstet et de Gynecol de Paris*, July, 1927, p 501) observed in thirty nine cases in a series of 200 childbirths a temporary or lasting retrodeviation of the uterus during the puerperium. Forceps delivery was required in twenty cases, but retroposition was noted in only three of these. Retroposition was not appreciably more frequent in multiparae, and permanent backward displacement originated as a rule after the first confinement. Of forty seven cases in which it was possible to decide whether puerperal retroposition was congenital or acquired twenty were congenital and twenty seven acquired. Contrary to expectation it was several times found that a uterus primarily retroverted or even retroflexed became anteplaced during the puerperium and even remained in this position during subsequent pregnancies. In forty eight patients it was possible to note the date on which retroposition was first observed. In 75 per cent it occurred from the sixteenth to the twenty eighth day. The author believes that puerperal retroposition of the uterus is favoured by the patient's quitting her bed early after labour rather than by too prolonged dorsal decubitus. In several cases a uterus which has preserved correct position for a week after the patient's first getting up has become retroverted as a consequence of a fall. Fruhnholz advocates medical supervision of puerperal patients between the third and sixth weeks, and for treatment of the backwardly placed uterus recommends manual reposition and massage rather than mechanical pressure by tampons or pessaries.

## Pathology.

#### 422 Basal Metabolism in Chronic Arthritis

L. T. SWAIN and L. M. SPERAR (*Boston Med and Surg Journ*, September 1st, 1927, p 350) have endeavoured to determine whether there is any change in the basal metabolism in chronic arthritis which would afford some explanation of the long standing employment of thyroid extract in this condition on empirical grounds. They accepted the classification of chronic arthritis which distinguishes three groups—namely, the infective, atrophic, and the hypertrophic. The patients, numbering 200, were of the hospital type, and in most cases the disease had lasted for a considerable time. There were ninety four patients of the infective type, their average age being 37.91, and the average duration of the disease 5.2 years, 62 per cent showed a normal metabolic rate, and there was a slight tendency towards the plus side in a small majority of the remainder. In fifty four atrophic cases the average age was 47.5 and the average duration of disease 6.6 years. In 67 per cent of these cases the metabolic rate was normal, and of the remaining patients there was a minus tendency in about 17 per cent. In the hypertrophic group there were fifty two cases, with an average age of 56.4 years, and a disease duration of 5.1 years. Of these, 54 per cent showed a normal basal metabolism, of the remainder there were far more on the minus than on the positive side. Inasmuch as the study has brought to light the existence of variation from the normal metabolic rate in 39 per cent of cases of chronic arthritis, the authors conclude that the rate should be estimated in all cases of this condition, so that by relieving a hypoboid state, which detected, clinical improvement could be assisted.

#### 423 Experimental Study of Alkalosis

K. SUZUKI (*Japanese Journ Med Sci*, III (vol 1, No 1), 1927, p 67), as the result of experiments on rabbits, comes to the following conclusions: (1) Alkalosis is a disease in which the acid base equilibrium of the body fluids has been disturbed and alkalinity is abnormally increased, with the consequence that the ratio of free and combined  $\text{CO}_2$  in the blood is smaller than normal. (2) The quantitative decrease of blood  $\text{CO}_2$  occurs not only in acidosis but also sometimes in alkalosis. (3) In alkalosis the blood pH shows considerable oscillations, so that the diagnosis must be made by estimation, not only of the blood  $\text{CO}_2$  but also of the blood pH. (4) Introduction of alkaline carbonates into the blood produces an uncompensated alkalosis, but if the disease is of very short duration and not fatal the blood  $\text{CO}_2$  very quickly returns to the normal. (5) The rabbit offers a strong resistance to increase of the blood pH, but not so much resistance to its decrease. (6) The animal is generally very susceptible to acidosis, but is usually very insensitive to alkalosis. (7) The intravenous injection of alkaline carbonate has a specific action on the blood pressure, which falls during the initial stage of the injection and then rises rapidly. (8) Alkalosis is not the immediate cause of tetany. (9) The anatomical findings in a rabbit which has died of alkalosis show no specific features.

#### 424 Bacteriology of Whooping cough

G. M. LAWSON and M. MUELLER (*Journ Amer Med Assoc*, July 23rd, 1927, p 275) examined 1,115 cultures from cases of whooping cough on a modified Bordet Gengou medium at the clinic of the Boston Floating Hospital and in its wards, and found that 259, or 23 per cent, showed *Bacillus pertussis*. Of 533 proved cases of whooping cough in this series 219, or 41 per cent, showed *Bacillus pertussis*, which in three cases they were able to isolate as early as twenty four days before the onset of the whoop. Although the proportion of positive cultures was lower than in the cases reported by Vejer and other Danish workers (87.7 per cent), in both series there was the same fall in the number of positive cultures as the disease progressed. It was noteworthy that in 23 cases the patients never whooped, the disease being either spontaneously mild or rendered so by prophylactic vaccination or serum treatment. Three cases were examples of second attacks of whooping cough which the authors consider are not so rare as is supposed, and usually take a mild form, sometimes without the characteristic whoop. They suggest that the existing quarantine period should be extended to include the catarrhal stage of the disease, and that a quarantine period of thirty days from the onset of the catarrhal symptoms would control 94 per cent of all possible spreaders of the disease as compared with only 62 per cent or less under the present regulations. They add that the mediums for cultivating this organism must be freshly prepared and properly inoculated. Single negative cultures are frequently misleading and repeated cultures on three successive days are advisable.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine.

### 425. Chronic Myocardial Insufficiency

C. L. GREFF (*Virnesse Med*, September 1927, p. 538) believes that "myocardial insufficiency is a more correct term than chronic myocarditis" that correct conceptions of the size and great variations of the heart are necessary for the detection of morbid enlargement and that a competent knowledge of the myocardial reserve, its peculiarities and therapeutic possibilities is needed for early diagnosis and treatment. Cardiac cases fall into two chief groups. The one covers the first three or four decades of life, includes the congenital abnormalities and shows a great proportion of frank primary endocardial lesions. The second dealt with in this paper, covers the later stages of persistent organic endocardial lesions. Both groups include many cases of myocardial exhaustion or inadequacy which occur in congenitally underpowered and usually toxic hearts. Probably only a few inadequate hearts associated with arterial hypertension owe their insufficiency to the latter condition. Chronic non-endocardial lesions are sequelae of toxicæmia, and decompensation itself tends to heighten arterial pressure. Toxic deficiency is the chief source of cardiac symptoms, apart from the bruits of certain lesions and many conditions affect this point. To diagnose and treat myocardial insufficiency radiography is absolutely necessary. The ratio of the diameter of the heart to the internal chest diameter at the end of inspiration must be determined and if this exceeds 33 to 40 percent an enlarged heart is present. Bilateral and equal peribronchial oedema often only diurnal, is one of the earliest signs. It is manifested first over the upper or middle part of the leg, and is absent at the ankle. Fatigue is an important subjective symptom, and varies from a mere sensation of heaviness in the legs to actual exhaustion. Dyspnoea on exertion is also an important sign, and abnormal inability to hold the breath is of great significance. Gas intolerance, symptoms and precordial pain and distress are common concomitants of myocardial insufficiency. The pain varies in intensity and is relatively common in the adult. Day drowsiness, early waking, nervousness, sleep and disturbing dreams are frequent symptoms in the elderly. Wise counsel and the proper regulation of habits and diet may suffice in treatment. Exercise under proper direction may be effective in minor cases, though absolute rest followed by carefully graduated physical activity may be indispensable. Too abrupt a resumption of exercise after absolute rest is dangerous. Greene concludes that the primary duty of the physician lies in the earlier detection of reserve impairment, the removal of existing sources of myocardial toxicæmia, and the timely rational, and maximal correction of remediable myocardial inadequacy.

### 426. Immunization Against Tuberculosis.

J. VAN BENEDE (*Bruxelles Med*, September 18th 1927, p. 1429) reports the results of the attempted immunization of infants with BCG vaccine at a centre for the preparation and distribution of the vaccine at Liege which was opened in August 1924. By the end of April 1927 the vaccine had been administered to 470 infants but the cases selected for analysis by van Beneden were those in which the vaccine had been given more than six months previously—namely 23 in 1924, 115 in 1925, and 34 in 1926. The actual report therefore, deals only with 172 cases, and in 70 of these no record was obtainable. Of the 16 infants followed since 1924 14 are in good health and of these 11 have been brought up in tuberculous families. Two infants died, one from whooping cough and the other from acute bronchitis. Only 53 of the 115 infants vaccinated in 1925 have been traced. Thirty four brought up in tuberculous surroundings are alive and well, eleven children in healthy families are also well. Three have died of gastro-enteritis, one of convulsions, one of diphtheria, one of acute bronchitis and one of whooping cough and one broncho-pneumonia which terminated in convulsions presumed to be due to tuberculous meningitis, no account is given of the remaining infant. Thirty two of the 1926 infants are in good health, one has died of convulsions. Van Beneden finds that the percentage results in his 100 traced cases work out similarly to those of Calmette. He discusses the various sources of infection through the placenta by a filterable virus of tuberculosis and of segregation of the infants of tuberculous parents but he thinks that pre-immunized children who die of tuberculosis during the early months of life were probably

infected by massive doses before the refractory period due to the vaccine was established. The author regards his results as encouraging, moreover he has not seen any ill effects from the administration of BCG.

### 427. Endemic Typhus in Australia.

I. S. HONE (*Med Journ of Australia*, August 13th, 1927, p. 213) summarizes observations upon endemic typhus in and around Adelaide from notes of over 80 cases during the past four years. The onset is sudden with severe headache which persists until the appearance of the rash from the fifth to the seventh day, commencing on the chest and abdomen and spreading over the body and extremities during the next forty eight hours. At first simulating typhoid the spots become more numerous resembling a scattered macular rash when fully developed. A characteristic of the rash is that at first sight only a few large macules or papules are seen but by continued observation a much more profuse rash is found to be present than was at first thought to be the case. When once the rash has developed and the headache lessened the general condition improves and the majority of patients recover. A well defined rash is characteristic but no case should be diagnosed without a confirmatory positive Weil Felix reaction. It must however be borne in mind that the reaction frequently cannot be obtained until deference has occurred while this lessens the value of the test for early diagnosis it enhances it in post-typhus pneumonia. The incubation period is about fourteen days. The dissemination of the disease appears to be closely associated with rats and mice, these rodents seem to harbour the virus without becoming themselves infected, typhus being spread by some other vector than the body louse. The appearance of cases in widely separated centres in the United States as well as those occurring in Adelaide each resembling mild typhus with a positive Weil Felix reaction seems to show that they are all instances of the same disease appearing in different parts of the world.

### 428. Chancroid in Paris.

M. BERNY (*These de Paris* 1927 No 49) shows by statistics from Professor Jeannel's patients at the Hospital St Louis that of recent years there has been a decided increase in the incidence of soft chancroid in Paris. The maximum number was reached in 1919 with 293 cases, in the following two years there was a fall to 159 and 51 respectively. In 1922, 1923 and 1924 the rise was gradual and in 1925 very rapid (198 cases). This tendency to increase continued in 1926 as during the first nine months of the year there were 183 cases. In some towns and countries on the other hand chancroid is tending to disappear especially in Lyons, Breslau, Austria and Denmark. The principal causes of the increase of the disease are first ignorance on the part of patients who have little notion of the most elementary principles of hygiene and the dangers of venereal infection and secondly the inadequately controlled immigration of large numbers of foreigners and the increase of prostitution due to economic conditions and neglect of proper supervision. The measures which Berny recommends to prevent further spread of the disease are education of the public especially of its younger members by leaflets, notices and lectures and encouragement of athletics, the medical examination of immigrants, stricter supervision of prostitution and early treatment of chancroid, especially by vaccine.

### 429. Prolonged Chorea in Encephalitis Lethargica.

ABADIE and AMIAT (*Journ de Med de Bordeaux et du Sud Ouest*, July 10th 1927, p. 517) record the case of a man aged 27 who in January 1920 developed epidemic encephalitis characterized by disturbance of sleep, and choreic movements which appeared at the onset of the disease and persisted for three years after the acute stage had subsided. They were then progressively replaced by a Parkinsonian syndrome which was at first confined to the left side so that for two years the patient was hemichoreic on the right side and hemiparkinsonian on the left. Subsequently he developed typical Parkinsonism characterized by slow movements, rigidity, tremors and slowness of intellectual operations. The authors think that this is the first case on record of prolonged chorea of encephalitic origin. The substitution of Parkinsonism for chorea of which examples have been recorded by Ramsay, Hunt, Sicard and Lesne and Barak is explained by the extension of the cerebral lesions which were a first predominant in the neo-striatum.

## 430 III Effects from Lumbar Puncture

L M WIEDER (*Amer Med Journ Sci*, June, 1927, p 854), who records an illustrative case states that Schonbeck in 1915 collected 71 cases of death following lumbar puncture. Of these, 37 had intracranial tumours, 13 recent cerebral hemorrhage, 7 various forms of meningitis, 4 were uraemic, 3 presented cysticercosis, and one echinococcus cysts. One patient had acute myelitis and one a cerebellar abscess with rupture into the cranial cavity and localized meningitis, one was a case of ticks and pneumonia in a child, and one of cerebral anaemia and pulmonary oedema following the administration of chloroform. Two others showed elongation of the cerebellar processes producing pressure of the medulla against the foramen magnum, one apparently being due to severe hydrocephalus, the other presenting only a moderate dilatation of the lateral ventricle. In the syphilitic patient routine lumbar puncture is a comparatively safe procedure, as death followed the operation in less than 1 in 13,000 cases at the department of dermatology and syphilology at Ann Arbor during the last fifteen years. In addition to aseptic technique only routine precautions such as subsequent rest with elevation of the foot of the bed are necessary in spinal puncture of the syphilitic patient. Wieder's case occurred in a woman, aged 33, of a thymic lymphatic constitution, who died two days after the lumbar puncture. The necropsy showed considerable leakage of cerebro spinal fluid in the lumbar region and cerebro spinal syphilis.

## 431 Exanthema Subitum

H K FABER and L B DICKEY (*Arch of Ped*, August, 1927, p 491) from observations of 26 cases and a study of about 550 recorded in the literature, come to the conclusion that the view is erroneous that exanthema subitum exhibits no pathological symptoms or signs apart from the fever and eruption. While in the majority of cases the disease runs a benign and relatively uneventful course, symptoms of considerable severity may occur, especially affecting the nervous system, these include malaise, drowsiness, in-omnia, severe headache, vomiting, and even generalized convulsions. In a large proportion of cases definite evidence of a nasopharyngeal infection is present. The disease may be communicable, with an incubation period as short as three or four days. Otitis media, suppurative lymphadenitis, and pyaemia are occasional complications.

## 432 Striae Atrophicae following Varicella

E APERT and MORNET (*Bull et Mem Soc Med des Hop de Paris*, June 16th, 1927, p 859) record the case of a girl, aged 14, the subject of initial disease, who, after a mild attack of varicella, developed a series of horizontal purplish striae on the right side of the thorax extending from the angle of the scapula to the last rib. There were also similar striae on the postero lateral aspect of the pelvis between the iliac crest and the upper margin of the great trochanter. This is thought to be the only case on record of unilateral thoracic striae following varicella. All the other reported cases of unilateral thoracic striae have been associated with pulmonary or pleural lesions.

## Surgery.

## 433 Chronic Epididymitis Simulating Tuberculosis

M BIEBL (*Zentralbl f Chir*, September 10th, 1927, p 2337) describes two cases of chronic epididymitis in which an erroneous diagnosis of tuberculosis was made. The first patient, aged 27, had no family history of tuberculosis and denied having had any venereal or other disease. There had been a painless swelling of the right epididymis for three weeks without any history of injury, an indefinite swelling as large as a walnut was felt in the lower pole of the organ. The skin was not adherent to the tumour, which was slightly tender on pressure. Clinically the diagnosis of tuberculous epididymitis appeared to be so certain that no exploratory operation was performed, but the right testis was removed. Histological examination showed a chronic fibrous epididymitis without any sign of tuberculosis. The second patient was a poorly nourished man, aged 66, who had had pleurisy six years previously. There was a history of tuberculosis in his father's family. The patient had not had any serious illness recently. The right testis had been swollen and slightly tender on pressure for two weeks. In the lower pole of the epididymis there was an elongated tumour as large as a thumb. Apparently the testis was not involved, and the spermatic cord and prostate were normal. The mine was free from sugar and albumin. During the operation an histological examination showed no evidence of tuberculosis, but, nevertheless, the right testis and epididymis were

removed, though the latter contained no caseating nodules there was evidence of abscess formation at the lower pole. The vas contained pus, but the tunica vaginalis was healthy. Histological examination showed a non-specific subacute suppurative epididymitis, involving the subjacent portion of the testis, but no evidence of tuberculous was obtained. Biebl remarks that these cases illustrate the difficulty in diagnosis of chronic non-specific diseases of the epididymis. The relatively short duration of the disease and the local prevalence of tuberculosis, especially of tuberculous epididymitis, led to the refusal to change the diagnosis in spite of the histological findings.

## 434 The Value of Periarterial Sympathectomy

THE value of Leiche's procedure of periarterial sympathectomy is doubted by A W ALLEN (*Boston Med and Surg Journ*, August 25th 1927, p 304), who reviews the results of eight sympathectomies performed since August, 1924, when he described an earlier series of fifteen sympathectomies. He states that the beneficial results of this operation depend on the secondary hyperaemia which follows the primary reaction of vasoconstriction. These reactions are fairly constant, and bring about relief of pain and rapid healing of chronic lesions. In most cases, however, these good results are temporary, the "secondary reaction" disappears in from three to eight weeks, leaving the patient in the same state as before operation. There is said to be a large psychic element in many cases, accounting for the relief of pain and the general improvement in the absence of any apparent local change. Allen's first series included eight cases of thromboangiitis obliterans, in only one of which was there definite improvement, in another case partial gangrene of toes healed without operation. Another patient was cured by diathermy, and sympathectomy failed in two cases of arterio-sclerosis, one with and the other without gangrene, in each of these two cases it was necessary to amputate the leg subsequently. In Allen's second series there was one case of spina bilidin with trophic ulcers and one of symphyomyelia with trophic ulcer, both healed quickly after sympathectomy. An arterio-sclerotic ulcer almost healed after the operation, and a patient with trophic neurosis was relieved of pain for six months. One chronic case of Raynaud's syndrome in a syphilitic patient, one case of thromboangiitis obliterans, one traumatic trophic neurosis, and a case of scleroderma were not relieved. Allen believes that without an adequate collateral circulation the operation is useless, and that periarterial sympathectomy has a very limited field. The temporary hyperaemia is more effective than that induced by other means, but patients benefited by it would heal with a longer period of palliative treatment.

435 B ULRICHS (*Zentralbl f Chir*, September 3rd, 1927, p 2297) describes the case of an ex-soldier who contracted frost bite in both feet in the winter of 1915-16. After removal of several gangrenous toes sympathectomy was performed in 1925, but this did not prevent recurrence of gangrene. In 1926 the left leg was removed below the knee, and seven days later the left thigh was amputated in the upper third. In 1927 Ulrichs decided to amputate the right thigh. There was no evidence that sympathectomy had any beneficial effect. Ulrichs refers to recorded cases of necrosis of the arterial wall and severe secondary haemorrhage, and states that the extensive literature on this subject indicates a marked change of opinion as regards the value of periarterial sympathectomy.

## 436 Otitis in Measles

E URBANTSCHITSCH (*Wien med Woch*, August 20th, 1927, p 1110) remarks that suppurative otitis media is a relatively frequent complication of measles. Its frequency varies from 5.1 to 15.4 per cent of all forms of acute otitis. He records his observations on measles otitis during the fourteen years that he has been otologist to the Kaiser Franz Josef Hofpital in Vienna, which has a large department for infectious diseases. From 1913 to 1919 he did not see a single case of measles which required opening of the mastoid, but during an epidemic which lasted from October, 1919, to March, 1920, he had to perform the operation on twenty mastoids, in eight cases on both sides and in four on one side only. All the patients were under 7 years of age. All the patients but one, in whom staphylococci and Gram positive bacilli were found, showed streptococci. All recovered except one, who died of pneumonia secondary to tuberculosis of the mastoid. Another severe epidemic of measles occurred in October, 1926 and lasted till the following April, 14.5 per cent of the cases developed otorrhoea, which in twelve patients led to operation—in nine on both sides and in three on one side only. All were under 6 years of age except one aged 16. In eleven the operation was performed between the third and eighth weeks of disease, and in one at the end of the first fortnight. From

the last patient *Streptococcus haemolyticus* was recovered, and from the rest *Streptococcus proteogenes*. All made an uneventful recovery except one, who developed pneumonia. Urban's conclusion that in measles mastoiditis on the whole runs a favourable course, though occasionally assumes a tuberculous form, and involvement of the lateral sinus develop

#### 437 Intestinal Obstruction Due to Biliary Calculi

A CHENET (*Revue de Chir.* No 4 1927 p 319) mentions that cases of intestinal obstruction due to biliary calculi are comparatively uncommon. They are usually accompanied by a high mortality, but the cause of death is often somewhat obscure. The author considers that the chief cause of death in intestinal obstruction is in alteration in the vitality of the gut itself. This allows infection of the peritoneum or an auto-intoxication of the whole organism through the peritoneal infection and this may occur even when the gut appears healthy by all ordinary methods of examination. Either the mucus itself and the vessels in the submucous layer become affected above the site of obstruction and the local pressure may produce a necrosis in the submucous layer which may affect the nutrition of the bowel itself. It is therefore suggested that the affected loop of bowel should be brought out-side the abdominal cavity, and after removal of the calculus the loop of gut be left piled off in the wound. The next day if all goes well and the gut appears viable it is returned to the peritoneal cavity and the wound is closed. This method is applicable to all cases and is not necessary in those seen early, further trial is suggested.

#### 438 Surgical Treatment of Pyloric Stenosis in Infants

E. THORPE, M. W. LOOKE and A. BROWN (*Imperial Journal of Child Medicine* 1927 p 180) believe that every case of pyloric stenosis should be submitted to the Rammstedt operation when diagnosed. They emphasize the importance in diagnosis of the four cardinal signs of the disease—namely, projectile vomiting, visible gastric peristalsis, palpable pyloric tumour and constipation. The pyloric tumour, they add, can be felt in almost every case if sufficient time is given to the examination. They record a series of 120 consecutive cases admitted to hospital, the Rammstedt operation was performed in each case with a mortality of 13.2 per cent. The diagnosis was confirmed in every instance at the operation. They believe that a large number of cases of apparent stenosis successfully treated by medical means are really cases of pylorospasm.

## Therapeutics

#### 439 Sanoerysin in Pulmonary Tuberculosis

C. F. FORD (*Indian Medical Gazette* July 1927 p 375) discusses the sanoerysin treatment of pulmonary tuberculosis, with special reference to Indian patients. He finds that the best results have been obtained in early exudative cases of not more than six months duration but benefit has also followed its use in older fibroid cases especially when accompanied by fresh exudative processes. The severe reactions following the earlier dosage have led to its reduction to the present dosage of from 0.10 to 0.25 gram increasing to 1 gram at intervals of from four to seven days for a complete course of ten to twelve doses. Contraindications for treatment are fever, albuminuria or any kidney affection, intestinal or abdominal tuberculosis or advanced cases showing signs of toxæmic cachexia. In favourable cases active symptoms appear to clear up more rapidly than with other forms of treatment. Of 60 Indian patients so treated 4 were early, 25 moderately advanced and 51 very advanced cases. 22 patients improved. The temperature became normal in 48 out of 35 patients confined to bed with pyrexia and improved before sanoerysin was given. Tubercle bacilli disappeared in 19 out of 54 cases with bacilli in the sputum previously. Most of the patients gained in weight and in many cases the physical signs cleared up well. Nine patients were unbenefitted and in 22 cases the treatment had to be suspended owing to intolerance of the "gold salt". The results of treatment in Indian patients were as good as those obtained elsewhere, although smaller doses had to be employed.

440 K. FABER (*Ugeskrift for Læger* August 25th 1927 p 70) publishes two series of cases of pulmonary tuberculosis treated with sanoerysin. In the first series the initial dose was half a gram and the subsequent doses consisted of 1 gram each given once a week. A somewhat smaller amount was given to febrile patients. This comparatively moderate dosage did not provoke the shock or fatalities for which the heroic dosage of the first sanoerysin period was responsible but in most cases there was a violent reaction, with

fever, rashes, loss of weight, albuminuria and occasionally diarrhoea. In the second series, which included the patients treated since July, 1925, the dose was much reduced, an initial dose of 20 or 25 mg being gradually increased to about 150 mg for each kilo of body weight—that is to about 60 to 100 g. Usually a total of six to nine injections was given. Under this cautious dosage the treatment changed its character completely. There was often no reaction and when reactions did occur they were much less severe. In the first series there were 46 cases, in the second there were 39. Only 12 patients were in the first stage of the disease and as many as 46 of the total of 85 patients were in the third stage. The proportion of third stage patients was a little higher in the first than in the second series. In both series tubercle bacilli were found in the sputum of 92 per cent of the patients. But whereas tubercle bacilli disappeared from the sputum of only 47 per cent of the patients in the first series, this sign of improvement was observed in 63.6 per cent of the patients in the second series. The average gain in weight of the patients in the first series was 4.4 kilo whereas it was 9.6 kilos for the patients in the second series. The proportion of patients showing various other signs of improvement was considerably higher in the second series and the author concludes that by reducing the dosage of sanoerysin and thereby avoiding violent reactions, he has obtained considerably better results.

#### 441 Lipase Treatment of Tuberculosis

ACCORDING TO MAPLE ROSE (*Brussels Medical Journal* 1927 p 1456) the tubercle bacillus does not secrete diffusible toxin, but acts by tissue destruction. Treatment should therefore be directed not to non-existent toxins but to the bacillus itself and to neutralizing the very toxic poisons resulting from secondary intercellular disintegration. Roger and Bossau have shown that the pulmonary aluminums are much more toxic than the muscular. The lungs are surrounded and penetrated by a well developed network of blood vessels and lymphatics are the seat of an intense resorption. This accounts for the greater severity of pulmonary than of other forms of tuberculosis. Tubercle bacilli owe their acid and alcohol resisting properties to their fatty waxy capsules and Calmette has stated that neither leucocytes nor lymphocytes alone in their digestive enzymes including lipase having this power. Bord has demonstrated that phagocytes though engulfing do not destroy the bacilli but are killed by them. Metchnikoff, Clerc, and other workers have shown that in animals the greater the amount of lipase present in the organism the greater is the resistance to tuberculous infection. Mayer and Morel have demonstrated in the lung the presence of a lipase similar to that of the pancreas and Bossau has proved that the lipase power of the tuberculous lung is considerably diminished. To increase this power Bord and Balvay have prepared a specific remedy termed Vebeol or V B 2 by placing six weeks old cultures of tubercle bacilli for several weeks in carefully purified vegetable oil. The bacilli killed by heating for an hour at 70° do not lose their biological properties and are dissolved without any modification. Vebeol has been shown to increase the pulmonary lipase power and on its administration the eosinophils increase in number the bacilli become granular less homogeneous and acid resistant and lose their virulence. The medication may be given either intravenously or injected directly into the lung through the trachea. It has been used extensively and many cases of improvement and even of cure have been reported. Its action may be aided by intratracheal only injections, which modify the pulmonary secretion and lessen the cough and fever.

#### 442 Serum Therapy in Pneumonia

H. S. BALDWIN and DOROTHY R. RHOADES (*Imperial Journal of Medical Science* August 1927 p 191) state that despite the characteristic of pneumococcus type II pneumonia the results of specific therapy have not been impressive. This is attributed to the fact that until quite recently it had been impossible to secure a serum of high protective value. Cecil Baldwin, Larsen and others have demonstrated that in type II pneumonia a bacteraemia with a high mortality rate occurs at some stage of the disease in from 33 to 43 per cent of cases and the present authors have found that this bacteraemia develops in the absence of sufficient protective substance which in excess is associated with recovery. W. H. Pitt in the winter of 1925-26 by immunizing a horse with type II pneumococci succeeded in obtaining a serum of 0.2 c.c. of which would protect a mouse against 0.2 c.c. of virulent culture. Twelve cases are reported in which this serum was administered. One of the characteristics of the natural production of a protective substance in the blood prior to and its increase following the administration of the immune serum. Four cases show the first appearance of a protective substance following the administration of the serum, no

bacteraemia being demonstrable before treatment or at any time during the course of the disease, in three cases a positive blood culture became negative after serum treatment, and in 4 cases treatment was of no avail. Baldwin and Rhoades conclude that death in pneumococcus Type II pneumonia usually occurs in patients who develop pneumococcus bacteraemia, and that when the blood remains sterile recovery is usual. With a highly potent Type II antipneumococcus serum it is possible to sterilize the blood in a certain number of cases of this disease. This sterilization is most frequently effected by administering the specific serum early in the disease, when the number of pneumococci in the blood is usually small. In early cases, where the organisms have not yet invaded the blood stream, the administration of the specific serum may establish a balance of protective substances in the blood and thereby lessen the chances of a subsequent bacteraemia.

#### 443 Preparation of Antiscarlatinal Serum

B. S. DZERJGOVSKY, S. E. FAIN, and A. B. PONOMAREV (*Arch. des Sci. Biolog.*, Leningrad, 1927, vol. XXVII, Nos 1-3, p. 121) found by experiment that the therapeutic effect of a serum obtained by treating horses with scarlet fever streptococci together with their toxin was not pronounced, although the antibacterial properties of the serum were very high. As the toxin component was increased the therapeutic effect of the obtained serum improved. At last the authors obtained a toxin giving the positive Dick's test in a dilution of 1 in 1,500. This toxin, freed from the bacterial bodies, was used for the immunization of horses. With the serum thus obtained 207 cases of scarlet fever have been treated, and the clinical results may be summarized as follows. There was visible improvement of the subjective symptoms and of the condition of the vascular and nervous systems. In the majority of cases there was a critical fall of the temperature in the first twenty-four hours following the injection of the serum, occasionally there was a gradual fall, taking two to three days. The injection of the serum on the first day of the disease prevented the appearance of the rash, if the injection was made on the second or third day the rash faded and did not spread. The angina was relieved. The power of the serum to prevent complications had not been definitely established.

### Laryngology and Otology.

#### 444 Morbid Changes in the Middle Ear Muscles

E. TORI (*Arch. Ital. di Otol.*, July 1927, p. 406) has studied microscopic preparations of 66 tensor tympani muscles and 57 stapedius muscles from 46 patients who died from various diseases, most of which were not connected with the ear. He found that when death was due to accidental causes in a healthy person there was a granular degeneration of the tensor tympani muscle fibres without there being any macroscopic changes in the middle ear. These lesions may be due to post mortem change, but in cases where there had been an acute or a chronic infective condition there were additional changes in the muscles, these consisted chiefly in an increase in connective tissue, which in old standing cases had become definitely fibrous. Fat was not noticeably increased except in cases of arterio-sclerosis, where the muscle fibres were comparatively few in number compared with the amount of fibrous and adipose tissue. In the stapedius muscles the degenerative processes were much less marked than in the tensor tympani, even in one ear in which the changes were marked in the latter muscle. The stapedius usually showed a less regular and less clearly marked stiltation than in ordinary muscle. There was as a rule considerable connective tissue, and notably many bundles of nerve fibres, but hardly ever any increase of fat. With suppuration in the middle ear there were often foci of suppuration and other degenerative changes in the muscles of the middle ear.

#### 445 Treatment of Inoperable Laryngeal Cancer by Radium and X Rays

CH. CORNIGLEY (*Rev. Med. de la Suisse Romande*, July 25th, 1927, p. 552) reports the case of a man, aged 77, who was admitted to hospital for a swelling of the neck of two months' duration. For three weeks he had had dysphagia, but could swallow liquids. Beneath and in front of the right sternomastoid there was a hard immobile, slightly tender tumour as large as a Mandarin orange. The muscle and the sub-jacent vessels were displaced by the tumour, and the veins were very congested. The right axillary region was much swollen, and in the right sinus pyramidalis there was an ulcer with slightly granulating margins, which was shown histologically to be a squamous celled carcinoma. In view of the patient's age and debilitated condition, and the presence of the large secondary growth in the neck, surgical treatment

was not advised, as it would have required primary ligature of the common carotid, and hemi or total laryngectomy. It was decided to administer a maximal dose of radium. A special vulcanite applicator, moulded to the right side of the larynx and the secondary growth, was made, charged with 240 mg. of radium bromide, filtered through 1.5 mm. of lead and 0.5 mm. of aluminium. This was applied for 47.5 hours, and very little reaction followed. A few hypodermic injections of 1 in 1,000 adrenaline solution were given as a prophylactic to toxic shock. Six days later the secondary tumour was reduced to the size of a pin. Twelve days after the removal of the applicator a very definite local erythema appeared, and was followed by desquamation and superficial ulceration, this was treated with castor oil. In three weeks the tumour had disappeared, but the dermatitis persisted for two months. A complementary course of treatment with x-rays followed for the purpose of attacking the primary laryngeal tumour, nine exposures, each lasting twenty-four minutes, being given. The laryngeal ulcer healed and the mucous membrane became apparently normal. On the death of the patient five months later from a different cause the necropsy showed that the laryngeal cancer and the secondary tumour had disappeared completely.

#### 446 Tuberculosis and Cartilage Formation in the Nasopharyngeal Tonsil

G. MARTUSCELLI (*Arch. Ital. di Otol.*, June, 1927, p. 363) describes the case of a boy, aged 18, from whom he removed a large pad of adenoids. On microscopic examination he found that the mass had lost all its adenoid structure and had become a large tuberculum with three nodules of hyaline cartilage. Nodules of cartilage are not uncommonly found in the palatine tonsil and have been thought to be remnants of the primitive pharyngeal arches. The author has found that the cartilaginous nodules are always very close to the capsule or along the course of a gland, and, while he agrees that the congenital factor is essential in the great majority of cases, he believes that a chronic inflammatory process is responsible for the growth of the nodule, and that in certain cases, such as the present one, cartilage is formed out of connective tissue by the action of prolonged inflammation. Tuberculosis of the adenoid mass is infrequent—the author states that it occurs in about 4 to 7 per cent of cases—but it may act as a latent focus, as in another case which he has observed, and later light up a widespread pulmonary and laryngeal tuberculosis. The co-existence of cartilage and tubercle in the same mass of adenoid tissue may be explained as the proliferation of cartilage-forming cells stimulated by chronic inflammation.

#### 447 Pneumococcal Oto-Mastoiditis

F. LEMARIE, M. LEVY BRUHL, and A. AUBIN (*Arch. Internat. de Laryngol.*, June, 1927, p. 641) describe the type of inflammation in the middle ear and mastoid process due to the *Pneumococcus mucosus*, or *pneumococcus III*, a Gram positive diplococcus occurring in short chains. The organism has a very special preference for bone and causes marked necrosis, the destruction is so rapid that in two or three days a large area of the meninges may be exposed. Meningitis is a frequent complication of this type of mastoiditis, and facial paralysis is not uncommon. The disease progresses in an insidious manner, without pain, temperature, or physical signs, and often the symptoms of meningitis are the first to call attention to the ear, this is in marked contrast to the more common type of mastoiditis. The treatment is essentially surgical and must be started as soon as a diagnosis is made. The mastoid antrum must be opened freely, all the mastoid cells removed, and all sequestra and inflamed areas of bone excised. If a bacteriological examination is made at the time of operation, auto-vaccinotherapy may be usefully employed as an adjunct to surgery.

### Obstetrics and Gynaecology.

#### 448 Treatment of Impacted Transverse Presentation

F. DEMUTH (*Zentralbl. f. Gynak.*, September 17th, 1927, p. 2403) thinks that, save in very exceptional cases where the foetus survives or where a high degree of pelvic contraction exists, impaction of the transversely presenting foetus demands decapitation. The operation must do as little damage as possible to the lower uterine segment, which, distended by foregoing forceps and repeated uterine contractions, stands in considerable danger of rupture. Decapitating instruments may be classified as blunt cutting or sawing. To the first group belong the single hook of Braun and the jointed double hook of Zweifel, of the former Demuth remarks that although given chief prominence in textbook descriptions and used as a routine in some clinics,

it is a crude and dangerous instrument which has now only an historical interest and should be abandoned. Zschel's instrument avoids the chief drawback of Braun's hook—namely dislocation of the head. Of the cutting decapitator the chief advocates are Friedman and the curved guillotine knife of Fern and Braun. The guillotine flexible saw (Libermont Bone, Doderlein) has been used with good results at Munich and elsewhere. In 1923 Blond introduced his decapitation thumb-still, to which is connected on one side a wire saw and on the other a ring, to be drawn around the fetal neck with the saw attached. In the Prague Clinic reference is made to the Fern Braun and Blond instrument, both of which have been found reliable and free from danger. Occasional cases of very tight impaction and/or contracted pelvis, the application of one of the instruments or its use when applied is found impracticable, the other is then tried, and if this fails recourse is had to decapitation by gradual section by repeated cuts with Skold's scissor. Twelve illustrative cases are described. In a primipara aged 23 the membranes had ruptured five days previously and pains had been present for two days with deeply impacted shoulder and occiput on upper limb protruding through the vulva, the child was still living. Transperitoneal cervical Caesarean section was performed, the foetus still living, was delivered with some difficulty by arm breech, and held in the order named and the mother survived a fibrile puerperium. In similar cases with minute infection Demuth remarks that extraperitoneal Caesarean section is even more risky than the transperitoneal operation, for cellulitis is more easily infected than the peritoneum, and injury to the uterus is more likely to occur in consequence of poor visibility in the operation field. For infected cases of impacted transverse presentation or with living foetus a less dangerous operation than cervical hysterectomy, although still fraught with considerable danger is that of Forster, in which after the classical section the empty uterus is temporarily sutured outside the abdominal wound. According to KCTFEBURG (ibid. p. 221) decapitation in cases of impacted transverse presentation is unnecessary. Instead the protruding arm should be pulled well down and the thorax perforated near the axilla, the thorax should now be eviscerated as also the abdomen after digital perforation of the diaphragm. The foetus can then be delivered with ease, either by the arm by a process of conduplicable corporis or by forcip application to the buttocks. It is claimed that laceration of the over-stretched lower uterine segment is thus avoided as also the difficulty which sometimes occurs in delivering the decapitated head. Delivery on the clunus is said to be safer for the patient, and considerably easier for the accoucheur, than when any mode of instrumental decapitation is employed.

#### 449 Sterility due to Uterine and Tubal Conditions

F. CHATILLON (*Gynecol. Obstet.*, August 1927, p. 81) discusses the various uterine causes of sterility. Congenital malformations are rarely amenable to surgical or other treatment. In the hypoplasia the fetal type of uterus is invariably sterile while the infantile and adolescent forms are amenable to treatment diathermy being the most frequently used and the most satisfactory. Cervical stenosis is probably a much rarer condition than it is usually considered in view of the minute size of the sperm cell. Anteversion the most important uterine displacement, is invariably associated with hypoplasia. Retroversion alone rarely causes sterility to do so it must be associated with disease of the uterus or with retroflexion. Another cause of sterility is atrophy of the uterus, for which no treatment is known. The various forms of endometritis, such as hypertrophy, hyperplasia or fibrosis of the mucosa are all difficult to diagnose with certainty without cauterizing and resist treatment. Ray applications have to the uterus or ovary radium therapy and opotherapy have all been tried in cases of sterility with varying success. Fibroids are a cause of abortion rather than sterility and myomectomy is the treatment of election. Malformations of the cervix, including congenital or pathological elongation and disorders such as cervicitis erosion and ulceration play an important part in the production of sterility they require energetic surgical treatment by amputation or excision.

450 E. DONAY (ibid. p. 126) deals with sterility of tubal origin. He describes the operation of insufflation of the Fallopian tubes with air or oxygen from the uterus in 8 to 10 per cent of cases permeability of the tube is re-established by this method either by the relief of spasm or by the relief of obstruction when the tube is blocked. Similarly injected when the tube is blocked by means of x-rays surgical procedure may then be employed such as salpingostomy or freeing the tube from adhesions. Verification of its permeability by insufflation at the time of operation is Donay's operation of election but salpingostomy, various forms of

salpingoplastic and salpingectomy with implantation of the ovary into the uterine cornua are operations which are practised. Favorable cases for surgical intervention are those due to pelvic adhesions of all kinds post-puerperal cases do well also, provided that medical treatment is also given. Operative measures are contraindicated when the ciliated epithelial lining of the tube has been destroyed (usually gonococcal cases) in old cases of hydrosalpinx and in those in which subacute pelvic peritonitis is still present since the occlusion is reproduced. Donay emphasizes the need for the greatest care and gentleness in operative technique to prevent adhesions being formed. In from 15 to 30 per cent of all cases of sterility the male partner is at fault, and complete examination of him should precede any treatment of the woman.

#### 451 Carcinoma of the Cervix Uteri

A. BONNER (*Israel Journ. Obstet. and Gynecol.*, August 1927, p. 17) reports a case of carcinoma of the cervix in a Jewess, aged 35. Only two cases of cervical carcinoma have been reported in Israel under 35 and this malady is relatively uncommon in Jewish women of all ages. The patient commenced menstruating at the age of 11 and metrorrhagia supervened a year later a thick foul vaginal discharge appeared and this was followed two or three months later by profuse haemorrhages. Vaginal examination showed a small cauliflower growth entirely replacing the cervix. Caustic excision of the growth was performed. Microscopically the tumour proved to be a papillary adenocarcinoma. At the time of reporting, nineteen months after the operation and two years after the onset of symptoms, the patient is well and neither the metrorrhagia nor the menses have reappeared. Ray therapy has been employed since the operation. Bonner adds that, though cervical carcinoma below the age of 25 is extremely rare it is not so between 20 and 30 and that many cases of this disease have been reported in nulliparous women.

#### 452 Irradiation of the Spleen for Metrorrhagia of Puberty

ACCORDING to C. MEPLETT (*J. v. d. Obstet. e. Gynecol. Pract.*, July, 1927, p. 281) the irregular and copious uterine haemorrhages occurring about puberty may be so severe as to lead to grave and dangerous anaemia. The results of treatment whether surgical or symptomatic are often disappointing, and time alone will bring about the re-establishment of the uterine and other hormone equilibrium with restoration of the regular menstrual rhythm and normal quantity. In some cases change of climate is beneficial, and in others diathermic applications to the true pelvis have been followed by good results. Merritt states, however, that in severe cases the most prompt and intense benefit is derived from treating the spleen by x-rays. The way in which these act is obscure, but the author reports twelve cases dealt with successfully by this means. He advises three applications—from the front behind, and the side respectively—given on successive days they are repeated during the fifth and eleventh or twelfth weeks. Diminution of haemorrhage and restoration of general health are brought about with great rapidity, the red blood cell count increases the platelets become more numerous, and the coagulation time is accelerated.

#### 453 Spinal Anaesthesia in Obstetrics

BRINDEAU and LANTUEJOL (*J. v. d. Obstet. e. Gynecol. de Paris*, April 1927, p. 243) in employing spinal anaesthesia during childbirth perform lumbar puncture and receive the cerebrospinal fluid in a tube containing 10 cc. of cocaine, the solution formed is slowly rejected. The puncture is preceded by subcutaneous injection of sparteine. In 25 cases the authors had two deaths both occurring shortly after the injection one patient was an obese alcoholic subject and the other had had seven or eight dry punctures. The authors remark that voluntary curvature of the lumbar vertebrae removal is difficult during advanced pregnancy so that lumbar puncture is not always easy apart from this from 4 to 5 per cent of patients experience incomplete anaesthesia. Nevertheless they are convinced that if devoid of danger spinal anaesthesia would be the ideal method for certain obstetrical purposes. Its most striking benefits are seen in abdominal Caesarean sections where corporal or cervical anaesthesia is described as incomparably more easy than under general anaesthesia. Pain is as a rule absent the fetus does not suffer haemorrhage is almost completely suppressed and after delivery of the child the uterus retracts so forcibly that eversion of the edges of the incision may be noticed. Spinal anaesthesia was used in 1-3 abdominal and in 2 vaginal Caesarean sections the latter were simplified by increased suppleness of the soft parts, but termination by version was necessary. In normal labour spinal anaesthesia is said to be contraindicated, too reflex expulsive pains are almost

abolished, so that extraction by forceps becomes necessary. In 26 cases of breech presentation spinal anaesthesia was found extremely helpful, here, as in 66 cases of forceps application in primiparae, delivery was greatly facilitated by reason of the paralysis of the vulval, perineal, vaginal, and cervical muscles. Spinal anaesthesia is not indicated when version is to be performed, or when in breech delivery a foot has to be pulled down, in these cases, in contrast with other observers, the authors have noted the manoeuvres to be rendered difficult by the increased force of uterine retraction and contraction.

## Pathology.

### 454 Quantitative Estimation of Albumin

LIPOWSKI (*Ued Klinik*, September 2nd, 1927, p 1340) describes a new method for estimating the amount of albumin in urine and cerebro spinal fluid. The fluid to be examined is slowly poured into a funnel lined with filter paper loosely covered with kieselguhr. The water clear filtrate is then roughly tested by the ring method to determine whether the albumin is abundant or only scanty in amount. From exact experiment by weighing it was found that urine containing 1 per 1,000 of albumin when diluted 100 times with water gave a just perceptible clouding on the addition of 1 cmm of a 10 per cent solution of acetic acid and potassium ferro cyanide. If the clouding appears with a dilution of 1 in 200 the urine contains 2 per 1,000 of albumin. With the help of a stand holding a number of graduated test tubes the clear filtered urine can be diluted to any desired dilution, and on addition of the acetic acid ferro cyanide solution it is possible to observe the dilution in which the clouding is just perceptible and to estimate with great accuracy the amount of albumin present in the fluid. The author claims that this dilution procedure is more accurate than Esbach's method, the smallest amount of albumin being precipitated, whereas by Esbach's method traces of albumin are not affected, the reaction of the fluid and its specific gravity need not be considered in Lipowski's test, and the temperature of the room is immaterial so that the dilution method can be used for any specimen of urine. Moreover, whereas Esbach's method takes twenty four hours, the dilution method gives the estimation in a few minutes.

### 455 The Effect of Exercise on the Blood Fat Content

J W T PATTERSON (*Biochem Journ*, vol xvi, No 4, 1927, p 958) has conducted a series of investigations on blood conditions after exercise, the five subjects being healthy medical students. The method of Stewart and White was followed in estimating the blood fat content, at first the blood sugar was determined by Benedict's method, but, as the results proved to be too high, that of Folin and Wu was later adopted. The cholesterol content was found by Blois's modification of the Autenrieth Funk process. Air samples for calculating the respiratory quotient were collected by the Douglas bag and analysed by means of Haldane's apparatus, the percentage of corpuscles was estimated by the haematocrit. In each case the same amount of exercise was performed (1) in the fasting state, and (2) after the oral administration of 100 grams of glucose. Patterson found that a definite and constant increase in the blood fat content occurred after exercise in the fasting individual, but not after the ingestion of glucose. This increase did not result from simple concentration of the blood, and may be due either to a definite response to a demand by the working cells for more fat or to failure to remove the fat from the blood stream. The author inclines to the former hypothesis, and suggests that the working cells only call on the fat when they have insufficient carbohydrate readily available. Certain indications point to a relationship existing between the blood fat and the blood sugar. In one case after the student had taken glucose while at rest the sugar rose in the first half hour and fell in the next, and the fat did exactly the reverse. This apparent relationship during resting, where the peak of the sugar curve coincided with the trough of the fat curve, was not maintained during exercise. Variations in the respiratory quotient were noticed, and these, taken in conjunction with the increase in the blood fat, might indicate that fat was being mobilized for conversion into carbohydrate. Investigation of the blood cholesterol seemed to show that it remained unaffected by exercise and unrelated to the definite blood fat variations.

### 456 Determination of Alcohol in the System

E ZEINER HENRIKSEN (*Norsk Mag f Laegevid*, July, 1927, Supplement) for the quantitative determination of small amounts of ethyl alcohol in the blood and urine employed the Nieloux Widmark potassium bichromate sulphuric acid method with Bang's iodometric reaction. The blood, urine, and other tissue fluids all show about the same concentration

of alcohol shortly after it has been taken by the mouth. For this reason it is concluded that the concentration of alcohol in the system can be determined by establishing that in the blood or urine. It is essential that the intervals between the taking of the various samples of urine should be as short as possible, since the longer the interval the greater is the difference between the amount of alcohol contained in the blood and that in the urine. Individual conditions also play an important part. Some observers have maintained that there is an essential difference between the excretion of alcohol in abstainers and that in persons accustomed to alcohol, on the assumption that the latter possess a more rapid power of combustion as regards alcohol. Zelner, Henriksen's experiments, however, do not bear out these differences. In the case of a confirmed alcoholic he found a high degree of alcohol concentration in the urine and a long period of excretion. Some observers have maintained that intoxication does not become obvious until the alcohol in the urine amounts to 3 per mille. The author, however, found that with an alcohol concentration in the blood of a little over 2 per mille there was a high degree of intoxication. The emise of the excretion of alcohol in the urine of a single individual taken at different times was found to be fairly constant when the conditions of the test were maintained as similar as possible. Increased diuresis after the consumption of alcohol was the rule, but was not found in every case. It is probable that numerous factors in this case are at work, such as the effect upon blood pressure, heart, vessels, kidneys. The author comes to the conclusion that investigations of the concentration of alcohol in the blood and urine are in certain cases of great importance in medical jurisprudence.

### 457

#### The Action of Insulin

G A HARROP (*Arch Int Med*, August 15th, 1927, p 216) compares the toxic symptoms produced by an overdose of insulin with those found in various other conditions, such as prolonged fasting or severe exercise, the cyclic vomiting of children, partial thyroidectomy, Addison's disease, and sclerodermia, in these the only common factor is a lowering of the blood sugar content to anything from 30 to 70 mg in 100 c cm. These symptoms consist chiefly in anger, collapse, sweating, lowered blood pressure, and sometimes syncope. Harrop divides the symptoms of insulin poisoning into the mild—namely, weakness, pallor, feelings of hunger, coldness or numbness of extremities, and occasional diplopia or tinnitus—and the more severe ones, resembling alcoholic intoxication, and often including delusions and subsequent amnesia, the collapse and syncope may pass into coma and death. He remarks that, nevertheless, hypoglycaemia *per se* is not always associated with these or any symptoms, nor is the raising of the blood sugar content to normal by the administration of sugar and orange juice invariably followed by their abatement. He suggests that insulin may have some other action, apart from producing hypoglycaemia, which is responsible for the production of the toxic effects.

### 458

#### The Haematological Response to Adrenaline

G CAREDDU (*Rev di Clin Pediat*, August, 1927, p 543) has studied the effect produced on the blood picture in 32 children by the intramuscular injection of adrenaline ebuloide (dose in proportion of 0.05 mg for each kilo of body weight). The injection was made three hours after a meal to avoid any leucocytosis due to digestion. Blood examinations were made before and fifteen minutes after the injection, and were repeated every quarter of an hour for the first hour. Of the 32 children 10 were in normal health and between the ages of 1½ months and 18 months, 12 suffered from an exudative lymphatic diathesis, their ages ranging from 1 month to 18 months, and 10 children between the ages of 6 and 12 years were scrofulous. With the exception of two patients with an existing leucocytosis of unknown origin, an adrenaleuc leucocytosis was observed in all the cases, this reached its maximum thirty minutes after the injection. The leucocyte formula varied at different intervals after the injection and was not uniform in all the individuals of the same group, in each of which there occurred at least three types of variation in the white cell picture: (1) a pure polynuclear reaction, (2) an initial mononuclear followed by a polynuclear phase, (3) a pure mononuclear reaction. From the varying frequency with which each group presented the different type of reaction it was possible to note the different reactions of the groups. The normal children showed a polynuclear reaction with only slight tendency to the biphasic type, the lymphatic cases showed more uniformly a pronounced mononucleosis, the scrofulous group were biphasic with marked polynuclear phase or else purely polynuclear. From a practical point of view the haematological reaction to adrenaline is not serviceable for the diagnosis of lymphatism, although with lymphatic subjects it gives a mononuclear and biphasic reaction.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

459 Generalized Reflexes Originating in the Viscera  
I. KNOTZ (*Monatsh. f. Med. u. Naturg.*, September 29th, 1927, p. 1231) has found that acute conditions of internal organs, especially such as are associated with rapid increase in tension as well as certain inflammatory conditions of the body coverings in which increased tissue tension is present may call for a widespread viscerotaneous and visceromuscular reflex responses in the corresponding half of the body such as hemic hyperaesthesia and hyperaesthesia, generally of one-sided increase of mucotonic and alterations in temperature. The observed taneous vaso-constriction and pallor of the skin is occasionally associated with a subjective sensation of cold in several cases of hiliary and renal colic but never in inflammatory conditions the response may affect only the cutaneous segment of the skin corresponding to the innervation of the viscera, or in severe cases with sensitive nervous systems it may spread to one whole side of the body. In inflammatory conditions however, the temperature of the affected side of the body is frequently higher than that of the other side, especially in the neighbourhood of the lesion. Cases of flushing of one cheek and one ear, nictal sweating, and difference in the size of the pupils have also been observed in similar circumstances though less frequently. The widespread "more primitive" type of response to stimulation is ascribed to diminished function of the inhibitory mechanism, the readiness with which this occurs depending on the "torpid" or neurotic nature of the individual. The conductivity in afferent nerve paths is, however, altered qualitatively as well as quantitatively, since for example, a stimulus ordinarily producing the sensation of touch is felt as pain when the hyper-irritable nerve is stimulated. The increase in muscle tone affects, apart from the trunk muscles, in the upper extremity mainly the triceps and in the lower the adductors and the gastrocnemius while the increased tension in the muscles of the neck may cause the head to be slightly inclined towards the side of the lesion with increased resistance to passive flexion forward or to the opposite side. The observation that injections—for example of tuberculin—sometimes produce more pain and greater increase of temperature on the side of the lesion than on the other side is also correlated by the author with the phenomena described previously. Knotz considers that mild unilateral hyperaesthesia such as prevents patients without obvious organic disease from sleeping on one side or the other may be helpful in diagnosing obscure or deep seated lesions.

460 Serum Prophylaxis in Measles and Pertussis  
J. T. CHRISTISON (*Minnesota Med.* October 1927, p. 599) reviews the literature and concludes that the most successful method of preventing or modifying the course of measles is to inject the serum of convalescent patients. When this is not available whole blood or adult serum may be used.

461 E. J. HENDERSON (*ibid.* p. 601) has found that a vaccine prepared from the Bordet Gengou bacillus is most effective as a prophylactic, but is also of great value in the early catarrhal stages of whooping cough. The vaccine should be freshly prepared and should be given in three doses of one billion, one and a half billion and two billions on alternate days. Care should be taken that this vaccine contains different strains of the bacillus. He adds that the immunity relative or absolute, lasts for a comparatively short time so that the vaccine should be injected only when there is suspicion of exposure to infection or in the presence of a widespread epidemic.

462 Transudative Epituberculous Pulmonary Infiltration  
G. CAUSSADE and A. TARDIEU (*Rev. de Med.* 1927, No 3, p. 283) report three cases of massive oedematous infiltration in tuberculous lungs which they designate "transudative." This oedema, rarely generalized, is more often localized in one pulmonary lobe, and shows the usual signs of neutrocytic oedema, cardiac, renal, or infective. The nodular or follicular lesions which give rise to it are rarely apparent to the naked eye. Histologically it is characterized by a pure transudation without any inflammatory reaction, fibrin, or leucocytes of varying density and extent there are present some discrete parenchymatous or peribronchial nodules with giant and epithelioid cells. Clinically this transudative oedema is shown by a large number of physical signs ranging from the symptoms of acute or subacute oedema to those of pulmonary

condensation. The most frequent indication is that of simple apical tuberculous infiltration or of softening. The excessive sero albuminous secretion is not always shown by sputa with specific characters, this may be due either to the great quantity of the expectoration or to the alveolar retention of the transudate. In radiograms this transudative type sometimes gives a shadow of extensive necro caseous lesions, but there may be no diminution of pulmonary transparency. This epituberculous transudation appears to be the substratum of areas of curable pulmonary tuberculosis, which explains the resolution which may occur. Differential diagnosis between this form and massive necro caseous infiltration is difficult. The pathogenic cause of this non inflammatory transudation is unknown. The authors believe that it may be due to a bacillary toxin acting at a short distance, or to invisible filterable forms of the tubercle bacillus. They add that Vaudremer has recently drawn attention to the part played by non acid resisting forms of tubercle bacilli in the pathogenesis of tuberculous pulmonary lesions not really productive.

463 Lung Infections due to the Pneumo-bacillus  
CITING Weichselbaum, Netter, and many other workers, A. LEMERIE and J. LEVESQUE (*Arch. Med. Chir. et Appareil Respir.*, April 2nd 1927, p. 97) maintain that the pneumo bacillus of Friedländer is the causal agent in three distinct types of respiratory disease pseudo membranous bronchitis intermediate between a pharyngitis and a pneumopathy, chronic bronchitis and pseudo-pneumonia which often ends in pulmonary necrosis and abscess. In the last form there is a great tendency to septicaemia and for the disease to extend to the pleura. The functional symptoms are much more marked than in pneumococcal pneumonia, and consist of an intense dyspnoea, a spasmodic, incessant cough, pain in the side, adynamia, facial enaciation with cyanosis, abundant sweating, and hyperleucocytosis. The sputum is characteristic being viscid blood stained compact and not frothy, yellowish brown, of a peculiar fetid odor, and very rich in the specific organisms. The authors emphasize the frequency of the following characteristics: the tendency to necrosis with a more or less diffuse suppuration of the lung, rapid cavity formation, the characteristic sputum, and the extreme frequency of septicaemia. The prognosis is extremely grave death supervening in the majority of cases. Ordinary treatment has little or no effect but pneumotomy has given encouraging results in a few cases and the use of vaccines and protein shock therapy appear to be indicated.

## Surgery.

464 Femoral Aneurysm  
D. SASSOWER (*Zentralbl. f. Chir.*, October 1st 1927, p. 223) refers to the difficulty in distinguishing an aneurysm from an abscess when thickening of the sac and thrombus formation have abolished pulsation and thrill. These pathological changes may produce further symptoms—such as pain, fever, and swelling, which, in the absence of the usual symptoms of aneurysm, render differential diagnosis difficult, especially when the swelling is very tense. In these cases an exploratory puncture may assist the diagnosis. Sassower describes a case which simulated a malignant growth. A man aged 32 had a tumour as large as a fist in Scarpa's triangle on the left side, this had commenced twenty years earlier as a painless swelling the size of a pigeon's egg but during the three months previous to his admission to hospital it had increased rapidly. There was no history of injury. The patient was thin, but apparently healthy otherwise. The tumour was rounded, well defined, and in some places was of a cartilaginous hardness. The overlying skin was livid atrophic slightly raised and traversed by numerous dilated veins. The inguinal glands were enlarged and hard and there was a large varicose nodule of the leg. Pulsation and thrill were absent and an exploratory puncture was negative. A diagnosis of malignant tumour was made. An operation was performed under spinal anaesthesia and the tumour was found to be a femoral aneurysm arising below the origin of the profunda femoris. The walls consisted of greatly thickened connective tissue, organized blood clot and scattered calcareous plaques. After ligation of the artery above and below the aneurysm the sac was dissected out. Recovery was uneventful. The author considers this case notable on account of the painless existence of the aneurysm.

for twenty years, and its lteney under the stress of heavy agricultural work and the hardships of war. The rapid growth of the tumour during the last month was due to dilatation of the sac and organization of the blood clot

#### 465 Saline Solution in Acute Intestinal Obstruction

L. P. COLEMAN (*Anesthesia and Analgesia*, October, 1927, p 210) reports observations on the use of hypotonic saline solution in acute intestinal obstruction. From a personal experience of 42 cases in the last six years he compares the first series of 20 cases, seen prior to his adoption of the salt solution in treatment, with the second series of 22 cases in which the patients received the same care and operative technique, but with the addition of a 3 per cent solution of sodium chloride injected subcutaneously, three quarts being given within twelve hours, or, as in one instance, 20 c cm of a 30 per cent solution being given intravenously twice a day. An operation mortality in the first series of 50 per cent contrasted with one of 11.1 per cent in the second series. Coleman suggests, therefore, that the toxæmia in acute intestinal obstruction can be neutralized by the free use of a 3 per cent solution of sodium chloride, which, in conjunction with operative relief, renders it possible to obtain a decided drop in the mortality rate.

#### 466 Varicose Veins

B. B. NICHOLSON (*Archives of Surgery*, September, 1927, p 351) finds that the occurrence of varicose veins is much more frequent than is generally assumed. In a series of 112 cases 70 were in males and 42 in females. Heredity appears to play an important part in the majority of cases, but pregnancy is only a secondary factor in the development of varices. In nearly 70 per cent of his patients the varices developed between the ages of 18 and 30 years, while both legs were affected about equally. The underlying condition in the process of the formation of varicose veins appears to be degenerative, and the later stages represent the results of a combination of deleterious influences. The valves act only in directing the blood stream towards the heart, and not in protecting the venous walls from static pressure. Treatment is often difficult and unsatisfactory, and great care must be taken in selecting cases for operation. In early cases elastic support should be tried. Advanced cases are best treated by surgery, the accepted method being excision. Nicholson recommends small incisions at intervals along the course of the vein and stripping out the vein. Various injecting agents were used with success in a number of cases.

#### 467 Treatment of Varicose Veins by Injections

H. O. MCPHEETERS (*Surg., Gynecol. and Obstet.*, October, 1927, p 541) advocates the injection treatment of varicose veins by the use of sclerosing solutions. The clinical results in 31 cases with 180 separate injections afford, in his opinion, conclusive evidence that the introduction of 20 per cent sodium chloride solution is superior to all other methods of treatment. The chief objection is the theoretical possibility of fatal embolism, but in a search through the literature McPheeters has traced only two deaths following the use of sclerosing solutions, one apparently due to fat embolism and the other to mercurial poisoning. The advantages of this method are that patients can follow their occupations and are spared hospital expense, the treatment can be easily repeated should there be recurrence. The technique is simple and, if care is exercised, all sloughing can be avoided. The main essentials are the use of a type of syringe which affords complete control of the needle point during both the injection of the solution and the aspiration of blood, taking care that the needle point is in the lumen, and immediately on its withdrawal the application of pressure with a gauze pad and bandage for from two to four days. The injection of salt solution may be followed by cramp-like pains in the leg below the site of injection, but these pass off in about a minute and are no more severe than many patients experience daily when on their feet. According to McPheeters the results are so uniformly satisfactory and so easily attained with a minimum of risk that the treatment will eventually supersede the surgical treatment of varicose veins.

#### 468 Typhoid Mastitis

I. SCHIFFMANN (*Deut. med. Woch.*, September 23rd, 1927, p 1643), who records an illustrative case, remarks that inflammation of the breast is one of the rare complications of typhoid fever. In his monograph on the surgical complications of the disease Madelung collected thirty cases from the literature up to 1923. Most of these cases were merely examples of infiltrations occurring during typhoid fever or in convalescence, and subsided spontaneously. In nine of Madelung's cases an abscess formed and a bacteriological examination was made in seven. In three of these typhoid bacilli were found, in two a pure culture, and in one associated with

*Staphylococcus aureus*. Schiffmann's case occurred in a woman, aged 26, who had been twice pregnant, and had had mastitis of both breasts after each of her confinements. Two years after the birth of her last child she contracted typhoid fever complicated by femoral thrombosis. Two months after recovery she developed mastitis, first in the right and then in the left breast, suppuration occurred in both and typhoid bacilli were found in pure culture. Slow recovery ensued.

## Therapeutics.

#### 469 Treatment of Diabetes by Synthaline.

SNAPPER (*Brussels Medical*, September 11th, 1927, p 1455) discusses the advantages and disadvantages of treating diabetes with synthaline, a derivative of guanidine, which is known to provoke hypoglycæmia in rabbits, but which also possesses strong neurotoxic properties. It is claimed for synthaline that it has stronger hypoglycæmic action than guanidine, it is less toxic, and its effects can be produced when administered by the mouth. Snapper was able to demonstrate, by operating on dogs made glycosuric by phloridzin and showing marked acidosis, that the administration of synthaline during starvation removed the acidosis, and that the effect persisted for several days. Whereas the action of insulin is immediate but transitory, the action of synthaline is slow and of longer duration. Insulin can be used in all severe cases of diabetes, but the use of synthaline is limited. It can only be employed in mild cases, when the food has to be greatly restricted in order to cause the disappearance of glucose from the urine, it may enable the diet to be improved. Snapper finds that the dose of synthaline is difficult to adjust. If given in sufficient amount to reduce the blood sugar it is apt to give rise to toxic dyspeptic symptoms, such as vomiting, diarrhoea, and anorexia, which in some cases appear with low insufficient doses, some patients being quite unable to tolerate the drug. Some clinicians have found that these symptoms can be relieved or removed if Riedel's decholin—a salt of sodium and hydrochloric acid—is given simultaneously with the synthaline. Snapper adds that the antidiabetic power of synthaline is limited, it is not possible to reduce the excretion of glucose by more than 30 grams daily, and this can usually be attained by a strict diet regime.

#### 470 Blood Transfusion in Infants

L. L. NUNN (*Minnesota Med.*, September, 1927, p 577) reports the case of an infant upon whom blood transfusion was performed by a method first introduced by Holmholz in 1915. In this procedure a needle, attached to a empty syringe, is inserted into the longitudinal sinus through the anterior fontanelle to the depth of about 1 cm. The needle is directed towards the external occipital protuberance, and it should have a short bevel to avoid puncturing the opposite wall of the sinus. When blood appears in the syringe the needle is firmly held and the syringe is replaced by a 20 c cm one containing the donor's blood, which is slowly injected. Nunn states that great care should be taken during the operation, and the continued presence of the needle within the sinus should be ascertained by frequent back pressure on the plunger. It is best to inject at the rate of 10 c cm a minute, as too rapid an injection is liable to cause intracranial pressure with fatal results. In this manner 60 to 100 c cm of blood can be introduced into the infant's venous system in a few minutes. The author adds that by utilizing the superior longitudinal sinus the problem of transfusion in infants is greatly simplified. This technique is efficacious, and superior to the clirito method, because it is more quickly performed, and the total amount injected is less. The introduction of relatively large amounts of fluid into an infant's vein is not desirable when there is no loss of body fluids.

#### 471 Protein Therapy of Pulmonary Tuberculosis

A. TIRONA (*Giorn. med. dell'osp. civ. di Venezia*, July-August, 1927, p 97) employed a non specific protein therapy in 46 cases in Tirona's third stage of pulmonary tuberculosis. He gave intramuscular injections of calcium caseinate. The first injection consisted of 2.5 c cm and the next of 5 c cm. The injections were given every other day if the reaction following the first injection had subsided. Although the treatment had no bad effects the results were not encouraging. In 25 cases no benefit was derived, but in 2 patients there was a real improvement, as shown by disappearance of fever, increase of weight, loss of cough and expectoration, and diminution of the moist sounds in the chest. In 3 cases, on the other hand, there was a decided aggravation, as shown by increase in the fever and other symptoms. The remaining 16 patients were unaffected.

## 472 Treatment of Ringworm with Thallium

J. H. T. DAVIES (*Brit Journ Child Dis*, July-September 1927, p 219) states that the advantages of thallium epilation over x-ray treatment of ringworm are as follows: There is no danger of a very burn; permanent alopecia, or even of incomplete epilation, provided that the correct dose, which can be weighed and is the same for everybody, is given. The question of damage to the brain does not arise and restless or imbecile children or babies are treated as easily as others. No expensive apparatus is required and the drug is no expensive. Epilation is to a much greater extent than with x-rays only auxiliary to the antipruritic treatment. In most thallium cases the infected stumps have to be extracted with forceps. The hair should be cut to about half an inch in length and the head washed every other day for six days and then daily. The infected areas should not be treated at first but the rest of the scalp should be rubbed with Whitfield's ointment after a shampoo once daily. After the infected areas are depilated they should be pilated with 4 per cent iodine in rectified spirit thrice daily for four days. As soon as the scalp is quite bald the whole of it is pigmented with iodine and then rubbed with non-mercurial ointment for three days. This iodine ointment sequence is continued for a further three weeks the scalp being examined for any stumps a least once a week and then discontinued in favour of daily rubbing with equal parts of oil of eucalyptus and lanoline until the new hair is well established.

## Radiology.

## 473 Serial Pyelography in Renal Surgery

By means of successive fluorium and direct observations after injection, 30 per cent sodium iodide solution through the ureters, R. BROGLIO (*Il Policlinico Sez Chir*, August 15th 1927, p 3-9) has discovered two varieties of movements of the kidney pelvis: (1) small movements in mass, giving the impression of sudden contractions of the whole kidney pelvis; (2) undulatory movements on the margin of the pelvis shade, of unequal rhythm, and directed from the exterior to the interior of the kidney. The normal kidney pelvis has a capacity of 3 to 12 c.c., and the approximate rate of emptying is about 1 c.c. per minute in the absence of pelvic infection. The time of evacuation varies with the amount of pelvic dilatation. In healthy persons it was found that the pelvis was emptied in 5 cases in three to four minutes and in 3 cases from five to six minutes; in 2 cases in 7 minutes and in one case the motility of the pelvis was inhibited for an hour by a too forcible injection of the opaque fluid through the ureter causing lumbar pain. In cases of ureteral stenosis the ureter being permeable to an ordinary catheter and the pelvis uninfected, the contractions of the kidney were violent and unequal in rhythm and duration. Evacuation of the kidney pelvis required as much as twelve minutes. After progressive dilatation of the ureter these symptoms disappeared and the patient has remained well for six months since. In a woman aged 22, with ureteral stenosis accompanied by pyelitis emptying of the pelvis lasted fifteen minutes the capacity being 13 c.c. with slight dilatation. Complete cure followed progressive dilatation of the ureter and washing out the renal pelvis with a solution of silver nitrate. In pyelitis the peristalsis was disordered and violent and the successive shadows appeared with great rapidity the pelvic capacity was usually normal and the evacuation exceedingly rapid. Treatment by washing out the kidney pelvis with a solution of silver nitrate resulted in cure in most cases. Cultures in the kidney pelvis were seen to move in synchronism with the peristaltic contraction. Broglia concludes that pyelography and pyelography should be a routine procedure in the surgical treatment of diseases of the kidney and ureters.

## 474 Utero salpingography

J. JAFCHO (*Surg Gynecol and Obstet* August 1927, p 129) considers utero salpingography—that is the radiological examination of the cavity of the uterus and Fallopian tubes after intruterine injections of iodized oil—to be a valuable method of diagnosis in selected cases. After an enema the night before and one on the morning of the examination the patient is placed in the lithotomy position as though for a vaginal operation on a table equipped with a Potter Bucky diaphragm. The patient is brought to the edge of the screen and a weighted speculum is placed in the vagina the cervix is grasped with a volsella cleared of mucus and swabbed with an applicator dipped in iodine which is washed off with alcohol. The vagina is swabbed with alcohol and dried, and the direction of the uterine cavity is determined with a sound A 20 c.c. Record syringe fitted with a modified Utzman Keyes urethral nozzle and a rubber tip 3 or 4 cm from the end to occlude the cervix and prevent the escape of

the fluid, is filled with warmed lipidol or iodipip up to the 15 c.c. mark and the nozzle is inserted into the uterus up to the rubber tip. The speculum is removed and the patient pushed higher up on the screen with the legs lowered. When rather more than 5 c.c. has been injected an x-ray picture is taken by the operator meanwhile maintaining a steady gentle pull on the cervix, at the same time pressing on the syringe to close the os completely. Care is taken that none of the oil flows out of the vagina on to the screen as its presence would spoil the plate. After two exposures have been made the nozzle is withdrawn and the patient is raised to allow the oil to drain from the uterus. Before removing the volsella a third plate is taken which invariably shows a shadow of the Fallopian tubes, if there are patent an accumulation of oil is seen in the pelvis near and round them. After twenty-four hours another photograph is taken and if no shadow in the pelvis persists another plate is exposed a week later. Jafcho claims that the procedure is entirely safe and harmless and that it has never given rise to iodism but strict aseptic precautions are necessary, with rest afterwards for at least a day.

## 475 Protective Measures in Screen Examinations

Realizing the feeble protection that is necessarily afforded when screening, S. GILBERT SCOTT (*Brit Journ of Radiol*, September 1927, p 327) adds four golden rules to the one laid down by the Protection Committee. These are: (1) work at a maximum distance; (2) use a minimum current; (3) waste no time; (4) use a small field. Distance being a very efficient filter the fluoroscope should be so designed that the face of the operator can never be nearer to the tube than thirty inches. The amount of current used should be the absolute minimum for the case in hand, 3 mm being ample for an average case. Each patient should be submitted to the same strict routine, regardless of any pathological conditions that may be present, the diagnosis not being decided upon until a complete examination has been made. The use of a small radiation field not only provides better protection but incidentally gives sharper definition to the area being investigated. As much as possible of the working apparatus should be enclosed in a cabinet as air tight and noise proof as possible. If these conditions are observed protective gloves need not be of a heavy type light protection is quite effective but should be provided for both the back and front. If the use of heavily protected gloves is deemed necessary the face must also be protected. It is a wise precaution to limit the number of screen examinations by any one person to about six daily.

## 476 Radium Treatment of Cancer of the Tongue.

A. EVANS and S. CLIDE (*Brit Journ of Surg*, July 1927, p 55) record the clinical findings in seventeen patients with cancer of the tongue treated by radium. The local changes were remarkable and the neoplasm disappeared in many cases. It is suggested that when the disease is operable it should be treated by radium rather than by excision but no claim is made as to the permanence of the results obtained. The authors find that the functional type of growth gives the best results and the smaller the size the better the prognosis. The primary growth is treated first and then the glands. Local anaesthesia is used and needles are inserted into the growth and left in position for six or eight days. After three months it is difficult in successful cases to find the site of the original growth, and the motility of the tongue returns to normal. The paramount difficulty is the treatment of the glandular area. A combination of surgical excision and radium therapy appears to be the most satisfactory method. In sixteen out of seventeen recorded cases the primary growth disappeared entirely after treatment.

## Obstetrics and Gynaecology

## 477 Mental Disorders of the Climacteric.

S. E. JONES and S. J. VINOUE (*Med Journ of Australia* August 27th 1927, p 283) have studied 811 case histories of female mental patients between the ages of 40 and 60 to find out which conditions were responsible for the increased incidence in mental disorders at the menopause. They state that the melancholic psychoses predominate in the simple and anxiety forms the prognosis is good in the agitated and stuporose less favourable. The delusional cases make up the greater number of this class and their prospects of recovery are less good. Mania cases formed an unexpectedly small group and here, again, the presence or absence of delusions influenced the prognosis. The paranoid group was also small and the prognosis was grave. Alcoholic psychoses accounted for 10 per cent and recoveries were numerous. In confusional cases the physical state was of great importance and practically decided the issue. Syphilis accounted for some of the

increased incidence, as the onset was usually during this period. Of the psychoneuroses neurasthenia was twice as common as hysteria. The increase in mental disorders was partly accounted for by the metabolic disturbances consequent on the cessation of ovarian function. Other factors were—the conjugal state, the rate being higher in single women, hereditary influences, which appeared to be of little consequence, and previous attacks. In melancholia the first attack was commonly at the climacteric, in mania it usually occurred earlier. Exciting causes fall into two groups—the physical and psychical. The authors add that there is no psychosis peculiar to the climacteric, but melancholia is its characteristic psychosis while neurasthenia is the characteristic neurosis. As regards artificial menopause, contrary to expectation the causal relation between this operation and the breakdown was not always clear. After hysterectomy or double oophorectomy there were a few cases in which mental disorder arose apparently as the direct result, but in the majority other factors came in, such as previous neurotic symptoms and domestic infelicity. In such cases the operation may have aggravated a pre-existing psychopathic tendency.

#### 478 Nitrous Oxide Analgesia in Childbirth

F. R. PASMAN (*Cronica medico qui de la Habana*, August, 1927, p. 421), from experience of nitrous oxide analgesia in twenty cases of delivery, concludes that it causes a remarkable disappearance of pain, there is no obvious diminution in the intensity and duration of the uterine contractions, there is no toxic effect on the mother or the child, and, in view of the absence of any toxic effect and its almost immediate elimination, it is considerably superior to ether, chloroform, and other anaesthetics more or less in vogue, which are known to have toxic effects. The only drawback to the anaesthetic is its high cost. Like other anaesthetics, it is contraindicated in conditions of asphyxia, acute tonsillitis, tumours of the neck, and any other obstructions in the respiratory tract. It should also be avoided in uncompensated heart disease, arterio-sclerosis, and pulmonary emphysema.

#### 479 Gonococcal Endocarditis following Labour

E. KLEIN (*Bull. Soc. d'Obstet. et de Gynéc.*, September, 1927, p. 524) reports a case of endocarditis, probably of gonococcal origin, in a pregnant married woman, aged 25. The patient, following an appendicectomy three years previously, had suffered from a marked leucorrhoea with very troublesome itching. Her recouchement, terminated after a long labour by forceps intervention under chloroform, was uneventful, and the child was well formed. The puerperium was normal for the first few days, excepting for an obstinate diarrhoea. Five days after birth the infant developed a purulent right ophthalmia, which, despite treatment, spread to the other eye. Examination of the pus revealed the presence of numerous gonococci. The husband had an anterior haemorrhagic discharge. Nine days after delivery the patient became slightly pyrexial, and a few days later vague pains were felt in the legs, particularly in the knee joints and calf muscles. There followed violent rigors, profuse sweats, intermittent diarrhoea, and other septicæmic symptoms. Auscultation of the heart revealed signs of infectious endocarditis. Despite all treatment the patient sank into coma, and died forty-eight days after her confinement. As the lochia had ceased when the first symptoms developed no bacteriological examination was possible, but blood cultures proved negative. Owing to the presence of gonococci in the ocular pus of the infant, the haemorrhagia in the husband, and the persistent leucorrhoea in the patient, Klein believes this to be a case of gonococcal septicæmia with cardiac localization.

## Pathology.

#### 480 The Mechanism of Perspiration

In conducting a series of experiments on perspiration Y. KUNO (*Journ. Orient. Med.*, September, 1927, p. 39) measured at the same time the amount of water discharged in five minutes from the skin at two different areas of 20 square centimetres each. Previous experiments had proved that measurements on such small areas satisfactorily revealed the state of sweating over the whole body. The temperatures of these parts of the skin and in the rectum were simultaneously determined. It was found that sweat secretion appeared and disappeared completely over the whole body, it was never local, the only difference at the various parts of the skin being in the absolute amount of sweat. This indicates that sweating is always caused by the action of the sweat centres, and that the excitation of these centres and the intensity of the nervous connections between these and the

sweat glands are the most important factors in sweating. Kuno forms the response of these centres to excitants, such as increased atmospheric temperature, the ability to perspire. The experiments showed that the height of the atmospheric temperature which just caused sweating was remarkably lower in the same individual during summer weather, on the day after a heavy drinking bout, or in a weakened condition after an illness. Sweat secretion appears to depend, therefore, on a variety of causes. Variation in the excitability of the sweat centres is the most important factor in changes in the ability to perspire, and it is probably brought about by alterations of the body temperature or by some chemical processes in the blood, changes of the skin temperature or of the blood supply being also possible contributory factors. With regard to the state of the ability to perspire the author finds that individuals fall into one of three categories: (1) Those who have little ability to perspire even when exposed to high temperatures, the heat consequently accumulating in their bodies. These are unsuited for rest in the tropics, or for any heavy manual labour. (2) Those who perspire in accordance with the necessities of the regulation of body temperature. These are normal. (3) Those who are always liable to sweat. This may be a sign of some abnormal condition, such as illness, and have a wide application for diagnostic purposes.

#### 481 The Effect of Heat on Antibodies

F. S. JONES (*Journ. Exper. Med.*, August, 1927, p. 291) has studied the effect of different temperatures on the destruction of antibodies. He immunized rabbits with various antigens, diluted the serum 1 in 2 to 1 in 5, and exposed it to temperatures of 65° to 90° C. for twenty minutes, the titre of the resulting serum was then compared with that of the unheated control. The experiments showed that antibody destruction increased gradually as the temperature was raised. Jones states that since the destruction is a function both of time and temperature it is unjustifiable to postulate the existence of a critical temperature, the most that can be said is that with the time factor kept constant the proportion of antibody destroyed at one temperature is so much greater than that at a lower temperature. For practical purposes, however, it is convenient to choose certain temperatures at which the destruction is practically complete in a given time, and to regard these temperatures as critical temperatures. Using the term "critical temperature" in this sense the author found striking differences in the reaction of different antibodies to heat. In one experiment an antiserum was prepared to a motile strain of the hog cholera bacillus, this serum had a titre of 1 in 2,560 when tested against a motile strain, and of 1 in 1,280 when tested against a non-motile strain. After the serum had been heated to 75° C. the titre to the motile strain was 1 in 1,280, whereas that to the non-motile strain had fallen to nil. In other words, the flagellar agglutinin was hardly altered, while the somatic agglutinin was completely destroyed by this temperature. Further work showed that the flagellar agglutinin was not completely destroyed even by a temperature of 90° C. He found that somatic agglutinin to the hog cholera bacillus and a precipitin to cow serum were both destroyed completely at 75° C., agglutinin to red cells was destroyed at 80° C., anti-sheep haemolysin at 85° C., and flagellar agglutinin to the hog cholera bacillus not completely even at 90° C. A warning is given that comparisons cannot be made between similar antibodies in the serum of different species of animals, for example, somatic agglutinin in rabbit serum resisted 70° C. for twenty minutes, while the same agglutinin in cow serum was destroyed at 65° C.

#### 482 Microprecipitation Test for Syphilis

M. G. PETERMAN (*Amer. Journ. Dis. Child.*, September, 1927, p. 404) suggests a modification of the precipitation test which is said to be simple and accurate. He uses a pipette graduated in divisions of 0.001 c.c., a hanging drop slide, and a thermometer. The Neumann and Gager antigen is used, this is made by extracting minced ox's heart several times with ether and then with alcohol, cholesterol being added to the final extract, which is then diluted with normal saline solution. After the serum of the patient has been inactivated at 56° C. for half an hour, 0.05 or 0.025 c.c. is placed in the concavity of a hanging drop slide, 0.01 or 0.005 c.c. of diluted antigen is added and stirred thoroughly. For optimal dilution of antigen is used. A glass cover slip is applied and the preparation is placed in an incubator at 37° C. for ten minutes, after which the slide is rotated to mix the solution thoroughly and is examined, preferably with the aid of a microscope. The results are interpreted according to the degree of precipitation, plus one, two, three, and four. In 500 tests the microprecipitation test was positive in 99.4 per cent of the cases in which syphilis was demonstrated, while the Wassermann reaction was positive in 91.9 per cent of these cases.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 483. Coincident Typhoid Fever and Malaria

L. H. HIRTZ (Journ. Amer. Med. Assoc., August 20th, 1927, p. 2586) who records an illness in this case states that there are many instances on record of the coexistence of typhoid and malaria in the same patient especially in malarial districts. Typhoid fever more frequently than other infectious appears to light up a latent malaria probably because of the severe strain of a wasting disease on the bodily functions. The first is most frequently the dominant disease, running a dormant malaria into activity. The malarial pyrexia however may alter the typhoid temperature curve at the onset during the course or most frequently in convalescence. Of 543 typhoid patients treated at the University Hospital Philadelphia, in the period 1895-1926 only two gave clinical and laboratory evidence of superimposed malarial infection. His case which occurred in a man aged 35 differed from the great majority of those on record in that the malaria appeared to be dominant. The temperature curve resembled that of double tertian infection and tertian parasites were demonstrated in the blood simultaneously. Cultures of *H. typhosus* were obtained from the faeces and urine and the Widal reaction which was negative on admission, became strongly positive eight and eleven days later. This fact and the rapidity with which the organism disappeared from the excreta under treatment showed that the patient was not merely a typhoid carrier. The course of the illness was mild the patient remaining afebrile after moderate doses of quinine. This case, therefore confirms the view that the course of the double infection is apt to be milder than that of either disease alone.

### 484. Syphilitic Diabetes

F. WOOD DUFRAE (Le Scalpel, September 3rd, 1927, p. 845) in view of the rarity of diabetes as a sequel of syphilis describes the case of a man aged 54 who complained of loss of weight, intense dysphagia without regurgitation and defæcto dyspnoea on exertion. A year previously there had been an increase in the area of aortic dullness and accentuation of the second aortic sound. Skiagrams showed considerable aortic enlargement with a small heart and definite dilatation of the upper third of the oesophagus above a constriction at the level of the transverse arch of the aorta and sufficient to arrest a small portion of the barium test meal. The patient had contracted syphilis at the age of 20, he had been treated and had had no recurrence. The liver was a little larger than normal and there was slight intestinal stasis. All reflexes were normal except that the knee jerks were absent. The urine contained much sugar, no albumin, some bile pigment but no urobilin bile acids or ketone bodies. There was a positive Wassermann blood reaction. When fasting the blood sugar figure was 184 mgms. dietary restriction and the administration of insulin were ineffective. Bismuth treatment was followed by progressive diminution of glycosuria, glycaemia and diuresis. The patient felt better and gained weight. One month after the commencement of the bismuth treatment the glycosuria and diuresis had disappeared permanently. The patient returned to work, the dyspnoea diminished and the weight increased. The dysphagia persisted, but caused little discomfort.

### 485. The Seborrhoeic Facies of Encephalitis

D. KRESTIN (Quart. Journ. Med., October 1927, p. 177) describes the seborrhoeic facies as a manifestation of post-encephalitic Parkinsonism and allied disorders. He emphasizes the importance of the association of organic brain disease with disorders attributable to disturbance of the vegetative nervous system as well as the particular control exercised by this system over cutaneous secretion. His conclusions are based upon 73 patients of whom 52 were suffering from chronic epidemic encephalitis lethargica, mostly with the typical Parkinsonian syndrome. The essential skin condition is an excessive secretion of sebum rendering the skin unusually greasy and shiny, especially on the face and generally associated with Parkinsonian rigidity and excessive salivation, and occasionally with excessive nasal secretion. It affects both sexes equally and is most frequent between the ages of 16 and 30. Other accompanying indications of involvement of the vegetative nervous mechanism are frequently seen, such as hyperidrosis, patchy hyperaemia, blotching of the skin, and coldness and blueness of the extremities.

Krestin suggests that since destructive lesions in the sub-stantia nigra and in the adjoining region of the base of the third ventricle are found in chronic encephalitis lethargica and allied conditions manifesting the Parkinsonian syndrome, and since there is evidence pointing to the existence in these areas of centres connected with the autonomic nervous system, it is possible that the secretory disturbances may depend upon lesions in the neighborhood of the third ventricle involving such centres.

### 486. Intoxication by Methyl Alcohol

ACCORDING to F. RIENDEAU (These de Paris 1927 No 211) prohibition in the United States has given rise to numerous more or less adulterated contraband varieties of alcohol. The principal substitute for ethyl alcohol is methyl alcohol which is commonly used for industrial purposes and is a violent protoplasmic poison with a selective affinity for the delicate structures of the eye. After absorption methyl alcohol becomes transformed by oxidation first into formic aldehyde and then into formic acid which are both corrosive poisons. Vomiting, abdominal pain and sudden blindness are symptoms suggesting methyl alcohol poisoning. Riendeau concludes that prohibition has not yielded the desired effect. Owing to the intense scale on which smuggling is carried out and the absence of control of numerous forms of alcohol contraband, toxic substances—especially methyl alcohol have given rise to a large number of severe and fatal cases of poisoning, which were very rare before the passing of the Volstead law.

### 487. Laryngeal Ictus in Whooping cough

H. BERGMANN (Deut. med. Woch. August 19th, 1927, p. 13) records a case in an otherwise healthy man aged 43 who had attacks of coughing during which he became unconscious for a few seconds. His wife and daughter were suffering from whooping cough at the time. As all other causes could be excluded such as faint epilepsy, asthma and syphilis, Bergmann attributes the ictus to whooping cough, especially as the condition was cured by codeine which he regards as almost a specific for whooping cough. The occurrence of laryngeal ictus in whooping cough seems first to have been described by Heberden.

## Surgery

### 488. Oesophageal Spasm as a Surgical Symptom.

P. R. MICHAEL (Nederl. Tijdschr. v. Genees., October 8th, 1927, p. 1519) states that at the meeting of the German Surgical Society in 1925 Sauerbruch reported a case of oesophageal diverticulum operated on by him in which the initial diagnosis was cardio-spasm. Michael himself has had a similar experience. In one case oesophago-copy was performed on a patient with spasm in the upper part of the oesophagus. In this case an ulcer apparently of a benign nature was found below the site of the spasm. He has also recently seen two cases of spasm of the lower end of the oesophagus or cardiac end of the stomach in one of which the spasm was associated with a large gastric tumour in this neighbourhood, while in the other case the spasm was due to gastric ulcer. Spasm of the oesophagus may therefore be a symptom of far reaching importance and both the clinician and the radiologist will be well advised to regard it as a symptom as long as possible and not as an independent disease until after other possible conditions have been excluded.

### Chronic Subdural Haematoma.

489 F. C. GRANT (Annals of Surgery, October 1927, p. 485) records notes of three cases which illustrate the possible importance of even a trivial cranial trauma in the etiology of obscure intracranial conditions. Pugh and Cushing have defined the microscopical differences in structure between the subdural blood clot resulting from trauma and that consequent upon chronic systemic disease. Whatever be underlying pathology is however the clot whether resulting from chronic inflammation of the dura during a wasting disease or produced by trauma gives rise to one clinical picture. Treatment consists in its removal preferably by decompression or reflection of an osteoplastic flap. Occasionally simple trephining over the lesion with the introduction of a cannula may result in evacuation of the fluid portion of the clot with apparently permanent relief and necessitate no further surgery.

have been reported following lumbar puncture, but this latter method is not better than direct drainage or complete operative exposure and removal of the clot. Since such subdural haemorrhage is often bilateral the contralateral dura should be inspected as a routine through a small trephine opening in order to determine the presence or absence of underlying blood, and this should always be done if the patient does not rally well after removal of the clot from one side. The onset of symptoms of intracranial pressure is insidious with an abrupt development of localizing signs of involvement of a definite cortical area. Grant adds that should there be a post-operative return of intracranial pressure, which may be due to cerebral oedema or an undiscovered contralateral clot, it seems useless to re-elevate the flap or relieve tension by lumbar puncture, the administration of hypertonic solutions by mouth and vein should be given a thorough trial.

#### 490 Operative Treatment of Recurrent Patellar Dislocation

ACCORDING to J VORSCHUTZ (*Zentralbl f Chir*, October 15th, 1927, p 2627) the knee joint should not be opened in the ideal operative treatment of this condition, since the most scrupulous asepsis will not always prevent infection. Having had disappointing results after plastic operations on the capsular ligament, the author has employed successfully the following method in four cases. A crescentic incision, commencing at the level of the upper inner border of the patella, is carried downwards, outwards, and finally upwards, at first concentrically with the patella and then prolonged to the level of the great trochanter. The skin over the patella is reflected, strips of fascia lata measuring 1.5 by 20 cm are dissected out and placed in warm normal saline solution, and the gap in the fascia lata is closed with catgut sutures. The fascial strips are folded lengthwise and threaded through the eyes of packing needles. Commencing at the medial portion of the patellar border the strips are passed at intervals of 1 cm in and out through the patellar margin. The ends are lightly secured with forceps, and then tied separately. At the patellar margin the ends of the strips measuring 4 or 5 cm, are crossed and fixed with catgut and silk to the inner edge of the ilio-tibial band and the periosteum of the internal condyle. When the patella is not in good position in the intercondylar groove, the ilio-tibial band is fixed to the outer patellar border. This operation renders it unnecessary to open the knee joint. Active and passive movements were commenced on the fourteenth day, and in two of the cases the patient had recovered completely in four weeks. Primary healing occurred in all four cases, in one patient a subcutaneous abscess necessitated drainage. The infolded fascia forms a thick band, which subsequently contracts and retains the patella in its normal position.

#### 491 Paget's Disease of the Nipple

J M WAINWRIGHT (*Amer Journ of Surg*, September, 1927, p 218) objects to the term "Paget's disease" being used to indicate many various conditions, some of a trivial character. He considers the condition to be a distinct entity, and that it is due to interference with nutrition where a cancer lies deeper in the breast, such a tumour may not at first be apparent clinically. It is not thought to be a neoplasia of the nipple, nor a squamous epithelioma, though Wainwright agrees that squamous epithelioma of the nipple is frequently associated with carcinoma in deeper portions of the breast. Such an association, in his opinion, can only be explained by Gye's hypothesis. The author describes and illustrates the morbid histology of a case he has investigated in which there were present four distinct varieties of breast carcinoma—namely, squamous epithelioma, comedo types, many separate foci of scirrhous carcinoma, and one nodule of the glandular type. Wainwright suggests that this protean manifestation is due to some change in the breast which resulted in the production of Gye's specific substance in many cells throughout the organ.

#### 492 Glandular Tuberculosis in an Adult

L BERNARD, M SLOMON, and M LELONG (*Ann de Med*, October, 1927, p 249) record the case of a woman, aged 30, who seven years after close and prolonged contact with a tuberculous patient, and one year after similar contact with another tuberculous subject, progressively developed a febrile condition of a typhoid character (typhobacillosis of Landouzy) which lasted three weeks and then subsided by lysis. The Vidal test was negative and the Pirquet test strongly positive. After a remission of three months, during which the temperature remained normal and the appetite excellent, although x-ray examinations showed the persistence of tracheo-bronchial adenopathy, the patient lost flesh, became febrile, sweated profusely, and developed almost simultaneously ulcero-creous peritoneal tuberculosis with enlargement of all the abdominal lymphatic glands and pulmonary tuberculosis starting at the hilum. This second stage lasted eight months, death being due to pericarditis.

## Theapeutics.

### 493 Liver Diet in the Treatment of Pernicious Anaemia

J HUSTON (*Amer Journ Med Sci*, October, 1927, p 520) records observations on thirty cases of pernicious anaemia in which the diet described by Minot and Murphy was given. With one exception the patients were kept in hospital for an average period of one month, and, when remissions were apparent, convalescence and further treatment were continued at home. That the liver was the important item in treatment was impressed on the patients. Personal idiosyncrasies (for which allowance was made) were frequent. Twenty nine of the cases developed remissions on this diet. Subjective improvement was noted within a few days and progressed so rapidly that, at the end of a month or a month and a half, the patients felt relatively well so far as ordinary activity was concerned. The remission persisted for a period as yet undetermined if the diet was continued, but relapses occurred when it was discontinued for very long. Achlorhydria persisted during the remissions. Numerical and other blood changes were usually evident about the first week, evidence of bone marrow regeneration being shown by the increase in reticulated, stippled, polychromatophilic, and nucleated erythrocytes, and of decreased blood destruction by the progressive fall in the amount of blood bilirubin. In view of the relatively high protein content of the diet, and because of the renal changes observed in some cases of pernicious anaemia and in patients at the age at which the disease occurs, Huston thinks that renal conditions should be carefully examined in both primary and secondary anaemias in patients placed on this diet.

494 O HANSEN and O STUB (*Udskrift f d Norske Laegeforening*, October 15th, 1927, p 1045) have treated 11 patients suffering from pernicious anaemia, and several other patients suffering from secondary anaemias, with a liver diet, according to the principles laid down by the American workers, Whipple, Minot, Murphy, and others. In 8 cases the pernicious anaemia was uncomplicated, and in the remaining 3 cases it was complicated by Graves's disease in one case, by syphilis in another, and by sepsis in a third. No marked effect was observed in the cases of secondary anaemia, although some of the patients stated that they felt definitely better. But the reaction to this treatment in the cases of pernicious anaemia was such that it seemed to deserve the title of "specific." In the case of a farmer, aged 57, an average of 388 grams of liver was consumed daily, 61 grams being taken at breakfast, 225 at dinner, and 102 at supper. About 100 grams of kidney were also eaten daily. This treatment was continued for about two months. The haemoglobin, which had been 31 per cent on admission to hospital, was 101 per cent on discharge. The number of red cells changed from 1.14 millions to 5.3 millions, the colour index from 1.40 to 0.95, and the white cells from 5,160 to 9,600. On discharge no nucleated red cells were demonstrable, and no polychromasia. After giving detailed records of some of their cases the authors draw attention to the regularity with which the disease responded to this treatment after the same interval of time. In all their cases improvement began between the fourth and sixth day of the treatment. In two cases practically normal figures were attained with regard to the haemoglobin and the red cells, and the authors ask whether complete arrest or cure of the disease can be claimed in such cases. They are sceptical on this point, and they note that measurements of the size of the red cells by the Buntzen-Gram method showed that though these cells diminished somewhat under this treatment they did not return to the perfectly normal size. The authors did not follow in every detail the directions given by Minot and Murphy, and they limited themselves to giving each patient an average of 200 grams of liver daily in addition to the standard hospital diet, which was supplemented by vegetables and fruit. They were surprised to find how well the patients tolerated the liver (that of calves, huddocks, sheep, and pigs) given both in the raw state and cooked.

### 495 Treatment of Whooping cough

R R STRUTHERS, MARY CHILDS, and W R KENNEDY (*Canadian Med Assoc Journ*, September, 1927, p 1042) emphasize the importance of treating children with whooping cough by rest in bed, combined with moist fresh air and direct sunlight. They think that artificial sunlight may help to shorten the period of cough after the cessation of the spasms, reduce the likelihood of fresh upper respiratory infection, and restore to the normal the enlarged tracheo-bronchial glands and the deranged calcium metabolism. They obtained good results from the rectal injection of a 20 per cent emulsion of ether in oil but do not intramuscular injections of ether as being painful and causing abscesses. Luminal in doses of 1/2 to 1 grain three times a day, for

children aged 6 to 8 years, was found effective in prolonging the intervals of rest and minimizing fear of the spasms. The authors also recommend vaccine treatment and have used cultures of *B. perussii* doses of 2 million to 10 million being given on every second or third day. Patients treated by this did not do so well as in former years, nevertheless this procedure, combined with large doses of a freely prepared vaccine, is the favourite treatment of the authors. They consider a period of four weeks after the onset of the disease sufficient for isolation.

#### 495. Neurovaccine Prophylaxis of Small pox

L. N. ANGLIO and F. V. CALDERON (*Ann. Intern. Med.*, September 10th 1927, p. 256) state that, almost simultaneously with Levaditi in France, Professor Caldeiro commenced his investigations on neurovaccine in the Spanish National Institute of Hygiene. The advantages of neurovaccine is compared with ordinary vaccine are stated as follows: (1) The clinical course of the vaccination. Among 20,000 cases in which it was used Caldeiro did not see a single example of hemorrhagic pustules, ulceration, generalized vaccinia, nervous symptoms, or erysipelas. The Spanish National Institute of Hygiene has distributed three million doses without having received any complaints apart from occasional failures, especially in the summer months. (2) Success of the prophylaxis. The present authors were successful in 95 out of 50 vaccinations with neurovaccine—a percentage not surpassed by the best dermiovaccine. (3) Rapidity of the preparation of lymph. Neurovaccine can be obtained ready for use in six days, whereas dermiovaccine requires at least a month for its preparation. (4) Purity. It hardly needs bacteriological examination as it is very pure. Neurovaccine is about 50 per cent cheaper than dermiovaccine.

## Ophthalmology

#### 497. Ultra violet Rays in Ophthalmology

BIRCH HIRSCHFELD (*Frit. Journ. ophthalmology*, October 19, 1927, p. 122) has found ultra violet rays useful in the treatment of corneal disease especially in cases of ulcus serpens. He uses a carbon arc lamp of 5 lamps with a quartz lens, a glass and a quartz bulb with iron sulphate to absorb the heat rays. He focuses the rays accurately upon the diseased area and gives an exposure lasting from three to six minutes once or twice a day. He does not claim to have obtained a cure in every case but considers that this method is a definite advance in the treatment of severe corneal conditions. The iron sulphate filter is to exclude the infra red rays and the violet glass the greater part of the light rays.

#### 498. Effect of Size of Stimulus in Perimetry

C. E. FERRELL and G. RAND (*Intern. Journ. Ophthalmol.*, June 1927, p. 399) describe their attempts to determine the effect of size or area of the coloured stimulus used in perimetry. They had previously experimented with the intensity of the stimulus and the brightness of pre-exposure and surrounding field on the size and shape of colour fields. They conclude that the size of the stimulus is nearly as important as its intensity in regard to visibility of colour in the peripheral field. By increasing the size of stimulus colour can be made visible in the extreme periphery of the field. The size of the stimulus produced the least effect with a pre-exposure and surrounding field of the brightness of the colour.

#### 499. Seasonal Incidence of Ulcus Serpens Corneae.

E. V. KNAPE (*Finska Läkarsällskapet Handlingar*, September, 1927, p. 780) draws attention to the lack of statistical evidence in support of the teaching that ulcus serpens corneae is more common during the warm seasons of the year than at other times. To check the truth of this teaching, and to investigate the incidence of this disease, he analysed the material available at the University Eye Hospital in Helsingfors making use of the out-patient as well as the in-patient material. In the ten year period 1908 to 1917 there were 34,777 patients and the number of cases of ulcus serpens was 386, or 1.1 per cent. The frequency of this complaint as among patients attending an eye hospital has been put as low as 2 per 1,000 and as high as 7 per cent. The latter figure being obtained from the University Eye Hospital in Oslo. Of the author's 386 patients as many as 272 were males. Thus the ratio of males to females was as 7 to 3, whereas the ratio of the total male to female attendances at the hospital was as 7 to 5. A classification of the patients according as they were town or country dwellers showed that the attendances of town dwellers numbered 22,324 and those of country dwellers 11,953. The cases of ulcus serpens coming from towns numbered 123 or 0.6 per cent, and the cases coming from country districts numbered 258 or 2.2 per

cent. This disease is therefore approximately four times more common among country dwellers than among town dwellers. The incidence of ulcus serpens from year to year during the ten year period was remarkably uniform, but when the cases were classified according to the months in which they occurred it was found that so far as town dwellers were concerned there was practically no difference in the monthly incidence of this disease throughout the year, but in the case of country dwellers it was most frequent from the middle of May till the middle of October, the greatest incidence being in August. Ulcus serpens is thus most frequent at a time when country dwellers are at work in the woods and fields, when the atmospheric temperature is at its highest.

#### 500. Treatment of Progressive Myopia.

M. WIENER (*Intern. Med. Assoc.*, August 20th, 1927, p. 594) suggests that in progressive myopia due to stretching of the sclerotic coat of the eye diet and exercise especially out of doors by producing an increase in the epinephrine output of the suprarenal glands, should help in arresting its progress. Acting on this assumption Wiener treated 1,000 cases with local instillations of epinephrine hydrochloride, 1 in 1,000 three times daily. Reading and close work were not restricted provided they did not interfere with daily regular outdoor exercise and a rational wholesome diet was given. The general improvement was so satisfactory and in some instances so remarkable that Wiener thinks these lines of treatment deserve further trial.

## Obstetrics and Gynaecology

#### 501. Prophylactic External Cephalic Version

G. F. GIBBERD (*Journ. Obstet. and Gynaecol. of the Brit. Sh. Empire*, Autumn No. 1927, p. 509) comments on the high foetal mortality in breech labour and strongly recommends external version as being free from serious risk for mother or foetus and usually effective. He thinks that this procedure should be tried as a routine soon after the thirty second week and if it fails a second attempt should be made after about a fortnight if necessary an anaesthetic should be given before it is decided that version is impossible. Gibberd states that since the difficulty lies in turning the long axis of the foetus past the short axis of the uterus it is most important to promote flexion of the foetus whereby the foetal ovoid shape becomes more spherical. The manipulation varies according as the breech or the head is the more accessible pole. In the first case the breech should receive most of the force applied, in the second case the head. In the left sacro anterior position for example, if the breech is more easily reached and displaced, it is pushed upwards and to the right with the right hand (to increase flexion) while the left hand gently presses the cephalic pole downwards and to the left. In the same position if the head is more easily accessible it is pushed downwards and to the right with the left hand while the right hand lifts the breech upwards and to the left. The most common source of difficulty is engagement of the breech which is often associated with extension of the legs before version is possible it is necessary to lift the breech out of the pelvis which may be facilitated by adopting the Trendelenburg position. After failure success may sometimes be secured by emptying the colon by enemata. In some cases the patient in bed for twenty-four hours and administered chloralhydrate and potassium bromide. In my pregnancy is a possible cause of difficulty in external version. Gibberd quotes figures from the Guy's Hospital maternity district which show that 105 uncomplicated breech deliveries in which show that 105 uncomplicated breech deliveries in which multiparae had a foetal mortality of 14 per cent and a maternal death rate of 1 per cent while 23 similar deliveries in primiparae had a foetal mortality of 23 per cent and a maternal death rate of 3.5 per cent—mortality rates which are considerably higher than those usually quoted and which support his recommendation of external version. This was employed in a series of 204 cases in which the child was ultimately delivered head first the foetal mortality was 2 per cent 14 per cent of live born infants died within ten days, but there was no maternal death. External version failed in 23 per cent of 232 trials it occurred spontaneously after success in about one-third of the cases of failure and was successful at second trial in about half the cases in which it was tried.

502. E. Maise (*Zeitschrift f. Gynäk.*, September 17th 1927, p. 241) advises external cephalic version in all cases of pelvic presentation discovered in routine ante-natal examination during the last few weeks of pregnancy. With the patient laid on her back he presses the foetal head in the direction of the foetal abdomen, at the same time pushing the pelvis

extremity in the direction of the foetal back. He states that the foetus responds to these pressures by active reflex movements, which have the effect of bringing about the desired version. This is usually accomplished with ease, but several trials may be necessary and sometimes the pelvic position is found to recur, so that repetition of the manoeuvre is needed.

### 503 Rupture of the Uterus

KUPFERBERG (*Zentralbl. f. Gynäk.*, September 17th, 1927, p 2421) does not agree that after complete rupture of the uterus, with a dead foetus lying in the abdominal cavity, extraction by the vagina should be performed. He states that the site of the rupture is often effectually plugged, so that bleeding is arrested by a portion of the foetus or by the placenta, by extraction of the foetus through the vagina the tear may be extended, haemorrhage may be renewed, and a fistula or renewed infection of the uterus may be favoured. A case is recorded in which immediately after passage of the foetus through the uterine tear, followed by vaginal delivery, the patient—whose general condition had up to then been good—died from internal haemorrhage before laparotomy could be performed. In such cases the treatment advised is the firm application of an abdominal binder, and admission to hospital for the abdomen to be opened.

### 504 Skene's Ducts in Pregnancy

J B BERNSTEIN and T K MONTGOMERY (*Urol. and Cut. Rev.*, September, 1927, p 577), from study of a large number of patients attending the prenatal clinic at Jefferson Medical College Hospital, have come to the following conclusions: (1) The urethra and Skene's ducts participate in the general pelvic and vaginal congestion incident to pregnancy. (2) As the result of this congestion there is protrusion of the urethra and prominence of Skene's ducts with frequent exposure of the ostia of the ducts. (3) This prominence is non-inflammatory in origin, and is to be distinguished from the inflammation of Skene's ducts, which is usually of gonorrhoeal origin. (4) There is a simple congestion of the ducts, which are of the same general hue as the surrounding vestibular mucosa, do not exude pus, do not present inflamed ostia, and are not associated with dysuria.

## Pathology.

### 505 *Treponema pallidum* in the Cerebro-spinal Fluid in General Paralysis

ACCORDING to A ROVASIO (*Riv. Sud. Amer. de endocrinol., immunol., y quimioter.*, September, 1927, p 716) only a few observers have endeavoured to detect the *Treponema pallidum* in the cerebro spinal fluid of general paralytics. In four cases examined by Wille and Kirchner and seven by Jeanselme, Schulmann, and Martin the results were absolutely negative. Rovasio has made a systematic study of the cerebro spinal fluid of general paralytic patients in the psychiatric hospital at Sassari. The following three methods of examination were used: (1) Direct microscopic examination of the fluid. Several hundred slides were examined without a single *treponema* being found. (2) Injection of the fluid into human subjects. Seven idiots, aged from 16 to 35, in whom the Wassermann, Sachs-Georgi, and Meinicke reactions were negative, were inoculated in the scrotum and the testes with the fluid four times in the course of six months to two years. (3) An equal number of rabbits were treated in the same way. The results in the idiots and the rabbits were completely negative, no lesions being found at the site of injection or in the testes of the rabbits and in one oeduced human testis. Rovasio therefore concludes that *Treponema pallidum* is entirely absent from the cerebro spinal fluid in general paralysis.

### 506 Physiological Variation in the Size of the Spleen

J BARCROFT and J G STEPHENS (*Journ. of Physiol.*, October 5th, 1927, p 1), as the result of experimental investigations, have found that the spleen contracts to about one half to one third of its size during exercise and to an even smaller volume at death or in consequence of severe haemorrhage. The amount of blood squeezed out during exercise is about one fifth of the volume in the circulation, the spleen then becoming pale, this phenomenon depends on the integrity of the splenic nerve supply. Psychological processes, related to culminate in violence may also cause the spleen to become pale and smaller. Its contraction is an early event in both haemorrhage and exercise, rather than a last attempt to increase the blood volume. Discussing the significance of the splenic response to exercise in regard to the relation of the blood volume to the vascular bed, and also to the augmentation of the amount of circulating blood, the authors state that the vascular bed in the region exercised increases, that on exercise the muscles need all the blood available and

that the spleen can produce a considerable quantity before the vital organs are drawn upon. It is unknown whether the amount added to the circulating blood by splenic contraction is sufficient to influence appreciably the circulation rate, a number of undetermined factors are concerned. J BARCROFT and L T POOLE (*ibid.*, p 23) have also made a number of experiments to ascertain the haemoglobin content of the blood of the spleen in contraction as compared with that in the general circulation. The extracutaneous spleen preparation was employed, readings were made with the haemometer and haemoglobinomoter, and blood was taken from the spleen and an ear vein. Immediately after exercise the splenic blood was usually little different from that of the general circulation, while subsequently it had a much higher corpuscle content, it contained a greater amount of haemoglobin, with a tendency for this to rise higher after exercise. Experiments by Binet seem to show that the spleen plays a considerable part in increasing the number of corpuscles both during asphyxia and exercise, though it may not be responsible for the whole phenomenon.

### 507 The Parathyroid Hormone and Callus Calcification

E P LEHMAN and W H COLE (*Journ. Amer. Med. Assoc.*, August 20th, 1927, p 587), disputing the assumption that because parathyroid extract injections increase the blood calcium there will therefore be more available calcium for deposit in fracture callus, conducted experiments upon white rats which show that so far from such injections hastening the calcification of callus their influence may rather tend to delay it. By comparing the breaking strength of callus of a fractured bone and that of the corresponding unfractured bone in normal rats and in rats injected with parathyroid extract the authors found that the average percentage of the strength of the normal bone shown by the healing callus at any age of fracture was less in the animals given parathyroid extract than in those not so treated. The untreated controls showed an average callus strength of 69.6 per cent of the strength of the normal bone as compared with 63.7 per cent in the rats given parathyroid injections. While such a difference is too slight to prove that parathyroid extract has an unfavourable influence on the calcification of callus it is quite sufficient to show that parathyroid extract does not exert any favourable influence in that direction. That parathyroid injections raise the blood calcium was shown by the fact that it was found to be almost 27 per cent higher in injected rats than in the controls killed at the same period after the fracture. The researches of Hunter and Aub indicate that the excess of calcium comes very largely from the bones, thus tending to reduce their calcium content, parathyroid extract injections seem to favour the withdrawal of calcium from callus and thus to delay union of fractures.

### 508 Glycaemia and Thyroid Radiotherapy

A TATTONI (*Il Morgagni*, September 15th, 1927, p 1521) records observations on the behaviour of the blood sugar after irradiation of the thyroid with large and small doses of x rays, his investigations were performed partly on dogs and partly on the subjects of Graves's disease. His conclusions are as follows: (1) Small doses are followed by a transient hyperglycaemia which soon disappears and is to be attributed to an endocrine change probably caused by discharge into the circulation of a large quantity of thyroid secretion. (2) The application of large doses of x rays to any part of the thyroid in dogs causes an upset of the normal equilibrium of carbohydrate metabolism manifested generally by a hyperglycaemia. (3) Irradiation of the thyroid in Graves's disease with the ordinary therapeutic dose also produces hyperglycaemia or has no effect on the amount of the blood sugar. (4) The hyperglycaemia following irradiation of the thyroid must be regarded as one of the ordinary biological reactions to x rays, and is to be explained by the physical, physico-chemical, and cellular changes produced. (5) The study of glycaemia, and especially of the curve of alimentary hyperglycaemia, may be of value in estimating the results of treatment, and therefore is of prognostic importance.

### 509 Sedimentation Rate of Erythrocytes

H B NEWHAM (*Quart. Journ. Med.*, July, 1927, p 371) finds that in a great variety of disease conditions the rate of sedimentation shows marked variations. He considers that little reliance can be placed upon this test as an aid to differential diagnosis. Where rapid sedimentation rates are present in all cases there is also hepatic derangement. This rapid rate is not influenced by the blood group of the person, moreover, rapidly of sedimentation occurs in anemic persons. Newham does not attribute the phenomenon to the presence of an excess of fibrinogen, but the cause would appear to reside in the corpuscles themselves, he believes that both physical and chemical changes are concerned.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

### 510. Fattening Action of Insulin in Pulmonary Tuberculosis.

J MORIN and L BOUASSE (*Bull de Med*, October, 1927, p. 363), record eight cases of pulmonary tuberculosis in various stages in patients aged from 18 to 25 treated by insulin. Subcutaneous injections were given about half an hour before meals. At first 5 units were given for two days, on the next two days two injections each of 5 units were administered, and then the dose was increased by 5 units every two days, so that in about eight days a total of 50 units in two injections was reached. The duration of the treatment was about a month. In some cases a total of 60 units a day in two injections of 30 units or three injections of 20 units was given. None of the patients showed any signs of intolerance attributable to hypoglycaemia such as weakness, tremors, sweats or nervousness, or only in a very slight degree but all had a more or less violent appetite a few hours after food which was immediately satisfied by ingestion of carbohydrate. No marked local reaction, urticarial eruption or gastro-intestinal disturbance was observed in any case nor did any of the patients show the slightest rise of temperature during the treatment. In all but two patients who were suffering from bilateral ulcer-casous tuberculosis there was a more or less progressive and considerable increase of weight which in some instances was maintained after cessation of the treatment. The mode of action of insulin in these cases is still under discussion. Some writers assign to insulin a direct action on the transmutation of carbohydrates into reserve fats while others attribute to it the power of retaining water in the tissues.

### 511. Typhoid Infection of the Joints.

A P H STRELL (*These de Paris* 1927 No 146) whose thesis contains the histories of eleven cases including that recently recorded by Schaeffer and Lhu (*LITOTOM* June 18th 1927 para. 638) remarks that while joint manifestations are by no means common in typhoid fever, cases of typhoid fever accompanied with symptoms of septic arthritis are decidedly exceptional. The clinical picture in such cases consists of two stages. The first which lasts from ten to twenty days on the average is characterized by articular symptoms which may involve all the joints, the large as well as the small. In the second stage the joint symptoms diminish or disappear entirely, and are replaced by the characteristic features of typhoid fever. The case of Gruet and Fortincau was unique in that there was an appreciable interval of six days between the articular manifestations and the typhoid symptoms. Apart from blood cultures, in the early stage and the Widal reaction later arthrotypoid can be diagnosed from the serious forms of acute articular rheumatism by the relative fixity of the joint symptoms, the course of the temperature, the absence of endocardial lesions and the inefficacy of sodium salicylate. The prognosis in arthrotypoid is grave since three of the eleven cases were fatal, death being due to adynamia and haemorrhagic and visceral complications.

### 512. Spinal Fluid Hypertension.

A TZANCK and P RENAU (*Bull et Mem Soc Med des Hôp de Paris*, November 3rd 1927, p. 144) state that hypertension, often considerable, of the cerebrospinal fluid occurs in a number of certain affections of the circulatory system apart from any nervous or meningeal condition. It may also be produced mechanically and be either physiological or experimental. In the first case it may be caused by the bodily position, movements, respiration and emotions, the pressure rising sometimes to five and even ten times the normal figure. The increase of cerebrospinal pressure caused by compression of the jugulars is the best known of the experimental hypertension. Claude Lemaître and Aubry believe that this is due to venous stasis following the compression of the thoracic and a purely mechanical explanation of the choroid plexus—a purely mechanical explanation. Wood and McWhinney have noted variations in cerebrospinal pressure after injections of hyper or hypotonic solutions and think that they are caused partly by changes in the volume of the cerebrum and partly by the mobility of the cerebrospinal fluid which, leaving the subarachnoid space, follows the perivascular sheaths. The present authors doubt this hypothesis and suggest that the change in pressure is due to variations in the blood volume. They state that an abrupt resection will cause an immediate lowering of the

spinal pressure, which is restored to normal by transfusion. Wollheim and Braudt have shown that the injection of hypotonic solutions in the treatment of arterial hypertension produces a diminution of the blood volume. The present authors maintain that it is owing to this diminution a mechanical cause, that the spinal pressure is lowered. In a second paper (ibid p. 1444) Tzanck and Renaud show that there is a direct association between the deep venous and spinal pressures in support of which statement they adduce the following facts. The subarachnoid space in which the cerebrospinal fluid circulates is in immediate contact with very rich venous plexuses, and between the two masses separated by a very supple wall a state of equilibrium exists. Secondly, in diseases causing venous stasis the spinal pressure is raised. A third evidential fact is the effect of venectomy and transfusion. The authors conclude that phenomena modifying cerebrospinal tension act through the blood volume, causing a deep venous hypertension and that spinal tension is an index of the deep venous pressure which can thus be estimated in affections of the circulatory system.

### 513. Pyrexia in Whooping cough.

P CAIRO (*La Pédatrie* October 1st, 1927 p. 1051) as the result of observation in an epidemic of pertussis concludes that there is a rise of temperature in uncomplicated whooping cough and that this is both due and proportionate to the severity of the attack. The pyrexia is only temporary and varies with the intensity of the paroxysm. The younger the child the more pronounced is the febrile reaction after the cough. In the author's opinion this rise in temperature is due to the excessive muscular action involved in the paroxysm and corresponds to the similar phenomena which follows a fit of crying.

### 514. Vaccination during Pregnancy.

B L LIEBERMAN (*Immun Jour Obstet and Gynecol* August, 1927 p. 217) as the result of observations at the Herman Hieffer Hospital, Detroit, on a series of 351 pregnant women vaccinated on admission and their newborn infants came to the following conclusions. Successful vaccination of the mother during pregnancy does not convey any specific immunity to the unborn infant inasmuch as 71 per cent of the infants react to vaccination. The immunity of the remaining 29 per cent is probably due to the general immunity which newborn infants possess and also to errors resulting from defective technique and feeble virus. Previous successful vaccinations in the mother with repeated subsequent failures to take although indicating immunity in the mother do not convey any immunity to the infant. Women may be vaccinated with safety at any period of their pregnancy. Newborn infants may be vaccinated on the first day after birth without any had immediate or remote effects. In clinics routine vaccination of mothers and infants is advisable.

## Surgery.

### 515. Angiobroma of the Tonsil.

G VIDAU (*Arch Ital di Otol* September 1927 p. 583) describes the case of a pedunculated tumour of the tonsil in a man aged 26. The symptoms were very slight and consisted of tickling in the throat, attacks of salivation and a tendency to vomit. On examination a tumour was found the size of a large kidney bean attached by a thin pedicle to the lower and anterior end part of the right tonsil. The pedicle to the lower and anterior end part of the right tonsil which though slightly enlarged appeared quite healthy. The tumour was removed by crushing the pedicle at its origin and separating by traction. Microscopic section revealed a matrix of fibrous connective tissue containing a large quantity of blood spaces cut transversely and longitudinally, the structure being that of an angiobroma. From his study of reports of a large number of cases of benign tumours of the tonsil the author draws the following conclusions. The tonsil has a great tendency to occur in young people and fibroma is more often than not attached by a thin pedicle. It is frequently very vascular and there may be haemorrhages into its interior. It is covered by a layer of epithelium the outer layers of which are keratinized. Most authors merely describe the size of the tumour and note the presence or absence of a pedicle, but have not recorded the minute structure. The prognosis is good except that in the case of

a large tumour with a long pedicle there is danger of impaction in the lumen, causing suffocation. The methods of removing consist in crushing the pedicle, removal with the hot or cold snare, and, in cases where the tumour is small, of morcellation.

### 56 Spontaneous Gangrene of the Extremities

ACCORDING TO D. LEWIS (*Archives of Surgery*, October, 1927, p. 613) lesions affecting the blood vessels of the extremities have been clearly differentiated and the clinical syndromes associated with them are well recognized. The etiology of the changes which lead to spontaneous gangrene are, however, still in a state of uncertainty. The clinical phenomena associated with arterio sclerotic gangrene are known. This condition is only rarely seen in the upper limb, and probably depends on the arrangement of the vessels in the leg and the extent of the thrombus. Amputation through the condyles is the best treatment in these cases. Death is rarely due to the operation, but to extension of the vascular disease or a terminal infection. Diabetic gangrene depends largely on the arterial changes rather than on the hyperglycaemia; it appears about ten years earlier in life than senile gangrene. In the relatively young gangrene is probably due to thrombo angitis obliterans, and a striking feature is the extensive collateral circulation which may develop. Recent thrombi are often found in the vessels after amputation in these cases. Treatment seems to be to force the collateral circulation ahead of the advancing thrombus, and ligation of the femoral artery has been performed with some success, pain is also relieved by this procedure.

### 57 Cancer of the Penis

J. RICAUD (*These de Paris*, 1927, No. 95), who records thirty-six cases in patients aged from 34 to 83, remarks that though cancer of the penis is rare before the age of 40 it is not uncommon disease, as in the course of fifteen years nearly sixty cases were treated in the urological department of the Hôpital Cochin, Paris. The condition was known in antiquity; it was described by Celsus, and later by Aëtius in the sixth century, and by Paulus Aegineta in the seventh. In the great majority of cases cancer of the penis is a primary condition, but occasionally the penis becomes invaded by a new growth arising in the prostate, scrotum, or bladder, or is affected by metastasis from a growth in the testis. Cancer of the penis most commonly arises in the balanopreputial groove, and then in order of frequency on the glans, meatus, prepuce, or body of the organ. Whatever the site of origin, two forms of the disease are described—namely, an ulcerative and a cauliflower-like growth. It is exceptional, however, to find absolutely pure examples of either form, a combination of the two is the rule. The glandular enlargement is often more of an inflammatory than a neoplastic character, and it is difficult to judge of its real nature from the naked eye appearance. Although the diagnosis of cancer of the penis is often easy a biopsy should always be performed, as it is the only means of preventing a needless mutilation. Treatment consists in amputation at a sufficient distance behind the growth, but leaving a stump for micturition. Removal of the glands should not be carried out until at least six weeks after amputation of the penis, when the subsidence of all inflammatory phenomena indicates that the glandular enlargement is really due to a new growth. As regards non-surgical treatment, the use of radium is said to be followed by fairly bad results. In early cases radium might be successful and save much loss of tissue.

### 518 Control of Haemorrhage in Rectal Cancer

J. F. MONTAGUE (*Med. Journ. and Record*, October 19th, 1927, p. 501) advocates the use of the haemostatic wadding "tabo amp" for the control of haemorrhage in cancer of the rectum. Composed essentially of finely shredded catgut, it has the appearance of cotton wadding or wool, and, being sterilizable by steam and completely absorbable by the body tissues, it can be safely left in a wound. Its value as a haemostatic is due to its property of incising; the coagulability of the blood on local application. A relatively small amount is sufficient, since it swells considerably when moistened. Montague's technique in the radium seed implantation treatment of cancer is to push a small tampon of cotton above the carcinoma after implantation in order to prevent, so far as is possible, contamination by liquid effusion above and to limit the fluidity of the content below. The lumen of the carcinoma-bearing bowel is then plugged with the tampon only moderately firmly to allow for the natural swelling when the material becomes wet, and a small plug of cotton is then placed below the carcinomatous area to retain the tampon in position until haemostasis has been obtained. The method is essentially the same as that employed in cases of cancer where bleeding, apart from radium implantation, requires treatment.

## Therapeutics.

### 519 Treatment of Broncho-pneumonia in Children

C. STAMM (*Monatsschrift für Kinderheilkunde*, September, 1927, p. 345), following the method advocated by Pospischill and Schlossmann, submitted a number of infants with primary broncho-pneumonia to continuous (day and night) open air treatment, usually without the aid of drugs, and obtained very satisfactory results, even in the changeable climate of Hamburg, especially when the treatment was combined with such postures as permitted the maximum range of movement to the diaphragm. It was found that dyspnoea was promptly relieved, restlessness diminished, and the children slept well, appetite also was much improved and the mortality rate fell. The results of treatment with a specific serum were inconclusive. In cases with cardiac weakness, general flaccidity of the muscles, low blood pressure, and feeble pulse, intramuscular injections of 20 to 50 c.c. of a 10 to 15 per cent glucose solution at body temperature, as recommended by Nassau, were found useful. Stamm, however, considers that this treatment is not without risk, and describes one case of an infant, aged nine weeks, with numerous patches of broncho-pneumonia in the left lung, a temperature of 100°, a pulse rate of 150 to 170, and a blood pressure of 75/40, in which no good reaction followed a mustard bath. Injections of 20 c.c. of 15 per cent glucose solution were repeated almost daily until a total of 400 c.c. had been given, while the child was unaided in the open air. The temperature fell to normal and the pulse remained good, but after an apyrexial interval of a fortnight a slight induration surrounding the site of injection in the left thigh began to spread until it reached one third of the way down the calf, suppuration occurred, and on incision gas as well as pus was evacuated, erysipelas subsequently developed and the child died. Bacteriological examination of the pus and fragments of tissue revealed staphylococci, *B. proteus*, and streptococci. On the analogy of the diabetic subject, in whom pyogenic organisms may become gas producers, and also because *B. proteus* produces gas when growing on dead tissue, Stamm suggests that the deposits of glucose in the tissues of a debilitated infant may act as a particularly suitable medium for the proliferation of these organisms.

520 According to H. GRENET (*Rev. med. Suisse rom.*, August 25th, 1927, p. 738) the problem of the specific treatment of broncho-pneumonia in children is rendered particularly difficult by the great variety of the bacterial flora. Anti-pneumococcal serum appears to be logically indicated, owing to the almost constant presence of the pneumococcus in broncho-pneumonia. It can act, however, on only one of the organisms concerned, and has proved to be uncertain in its results. The value of anti-streptococcal serum has not yet been established. Numerous successes have been attributed to treatment by vaccines, especially those of Minet, Riquet and Sorez, Weill and Dufont, and Dacheux. D'Oelsnitz's method of combined serum and vaccine treatment is of considerable theoretical interest and deserves a close examination, but it is not certain at present that it shows better results than vaccine therapy alone.

### 521 Cresopirine in Acute Articular Rheumatism

RAGOUNEAU (*Journal de Thérapie Française*, October, 1927, p. 145) reports three cases of acute articular rheumatism treated successfully by cresopirine (acetyl ortho cresothio acid), a derivative of the preparation of this drug appeared in the BRITISH MEDICAL JOURNAL on April 2nd, 1927 (p. 635). Ragouneau's patients had previously been ineffectually treated with sodium salicylate in both average and high doses. On administering cresopirine a rapid cure was effected in all the cases, in eight, four, and five days respectively. The dose for an adult is 10 grains (about 2½ drachms) in the twenty-four hours, and for an infant 4 grains (about 1 drachm). Ragouneau remarks on the rapid action of cresopirine in inducing a state of well-being owing to the subsidence of the fever and pain. He adds that it is always well tolerated, has no action on the heart, kidneys, or alimentary tract, and never causes tinnitus aurium or vertigo. He considers it markedly superior to sodium salicylate.

### 522 Therapeutic Injections of Distilled Water

T. LE BOUTILLIER (*Journal de Médecine de Bordeaux et du Sud-Ouest*, October 25th, 1927, p. 767) describes the striking benefits obtained from the intravenous or intramuscular injection of three distilled water in over 700 cases, the diseases so treated being sciatica, lumbago, arthritis, neuritis, tic douloureux, lobular pneumonia and broncho-pneumonia, chronic diarrhoea from the nose and ears, in convalescent chronic diphtheria and scarlet fever, hay asthma, and in cases of acidosis with or without cyclic vomiting. The

water, distilled three times, is put into ampoules and is then autoclaved to ensure sterility. Triple distillation is performed because certain poisons can be carried over from the first to the second distillate. The use of freshly distilled water is advised in order to avoid the possibility of disintegration of the glass in the water. The initial doses recommended are for infants and children up to 12 years, 0.5 to 1 c.c., from 12 to 50 years, 1 to 1.5 c.c., and after 50 years, 1 c.c. The dose should be increased by only 0.5 c.c. at a time to a maximum of 2 to 3 c.c. By observing these doses a reaction is rarely produced. Repetition should be guided by the result obtained from the first injection, and in acute conditions the doses should be smaller and more frequently repeated than in non acute or chronic cases. Intravenous is preferable to intramuscular injection, since the water reaches the blood immediately and in this latter the pain caused by the injection, though only lasting ten to fifteen minutes, is often extreme. A 25 cc syringe and a 26 gauge needle should be used for the injections. The action of distilled water is of a biochemical nature causing haemolysis. The erythrocytes break down, and their contents (oxy haemoglobin, lecithin, salt, album ferment and enzymes) are set free in the blood plasma. The blood thus assumes antitoxic and haemecidal properties and the action of the water is that of a foreign protein. After the injections there is a very slight increase in the erythrocytes, no change occurs in the leucocytes, the haemoglobin is increased from 2 to 4 per cent, and the coagulation time of the blood is decreased. Le Boulanger adds that the best results from this treatment have been obtained in cases of infantile erythraemia, these being more rapidly cured than by any other method and that though not a panacea, the benefits obtained in other conditions from this therapy warrant its further trial.

## 522                      The Use of Ovarian Extracts.

W P GRAVES (*Journal Amer Med Ass* 1930, October 15th 1927, p. 1603) finds that ovarian substances are almost specific in the treatment of hot flu like and the vasomotor disturbances of the menopause but is of little value in permanent amenorrhoea with hypoplasia or in the treatment of minor rhagia and metrorrhagia. It has proved useful in certain conditions of menstrual inefficiency and occasionally in essential dysmenorrhoea unassociated with marked hypoplasia. It has also proved effective in some cases of deficient ovulation. Graves considers preparations of the whole ovary or of the ovarian residue more efficacious than those of the corpus luteum alone since they contain the more highly potent hormone of the follicles and are free from toxic and inhibitory elements. He emphasizes the importance of using extracts of fresh glands.

## Disease in Childhood

## 524. Addison's Disease in Children

521. Addison's Disease in Children  
F. MORABITO (La Pediatría) September 15th 1927 p 569; in view of the rarity of Addison's disease in young children publishes two cases occurring in a brother and sister aged respectively 7 and 10. Both children had been ill for about nine months, and were wasting. The boy was p<sub>u</sub>nted in the characteristic manner and the girl was generally bronzed. They both suffered from progressive asthenia affecting the psychical as well as the physical functions. The boy complained of giddiness, anorexia and hypotension were marked in both cases. Pharmacodynamic tests in these cases the Wassermann and von Pirquet reactions were strongly positive. There was a slight polycythaemia and the eosinophil content was increased, there was some hypocalcaemia.

## 525. Breast-feeding in Full term Infants

525. **Breast-feeding in Full term infants**  
EDNA M HAYWARD and LOUISE MOWBRAY (*Boston Med and Surg Jour* September 29 b, 1927 p 515) draw conclusions as regards the feeding of full term newborn infants from a series of 651 cases. Under the previous three hour schedule of breast feedings too large a percent age of the babies were being discharged without having regained their birth weight. For the last year under a four hour schedule each breast was used for ten minutes so that the infant obtained a twenty minutes feeding period as before and was less frequently disturbed. The mother enjoyed greater comfort since neither breast became excessively full. Statistics in the charts of 571 breast fed infants during the first four months after the establishment of the four hour schedule compared with those from an equal number during four months under the three hour schedule show the distinct advantage of the former. Of 90 discharged on the ninth tenth and eleventh

days 40 were above birth weight on the four hour schedule as compared with 15 on the three hour schedule. Of 205 discharges on the twelfth and thirteenth days, 99 were above birth weight on the four hour schedule as against 61 on the three hour schedule, and of 76 discharged on the fourteenth and fifteenth days 43 were above birth weight on the four hour schedule as compared with 23 on the three hour schedule.

## 526                      Adenoids in Early Infancy

14. H. CAROLY (*These de Paris*, 1927 No 199), who records 17 personal cases in infants under 6 months of age, states that adenoids are generally due to prolonged infections or intoxications. Though frequent in the young child they are rare in the infant. Below the age of 6 months heredity alone is responsible—syphilis, tuberculosis, alcoholism, arthritis, and various chronic intoxications in the parents being the cause of the condition. Of 1,560 cases of adenoids treated at the Hôpital de la Clinique Despuys, Paris in the course of fifteen months, 89 or 6 percent of the patients were under 6 months of age and 17 of them or 20 per cent were the subject of congenital syphilis. An intensive and prolonged antisyphilitic treatment was adopted, and had a successful result on the enlarged liver and spleen, the specific coryza and the general condition but it had little effect on the adenoids, and surgical treatment was always needed sooner or later. Although adenoids crumbe are compared to the chancre mucosus, tubercles and gumma which all contain the common infecting element the spirochaete they represent one of the dystrophies caused by syphilis.

## Thrush

527  
H. K. ALBER and ESTHER B. CLARK (*Imperial College, London*) describe an epidemic of thrush among the babies nearly all healthy and vigorous in the private ward of a hospital. The source was eventually traced to heavy accumulations of dust in places difficult of access and invisible to casual inspection. Treatment with a freshly prepared 1 per cent aqueous solution of gentian violet is recommended the applications being made at least one hour after feeding. The mouth is gently cleaned with several cotton swabs to remove the adherent mucus and the gentian violet solution is applied freely first to the affected area and then over the tongue and in the bucco-gingival folds. The treatment is repeated once or twice daily for at least three successive days, and on alternate days thereafter for from one to two weeks. The mothers' breasts are carefully cleaned with soap and water before each nursing and the first few drops of milk are discarded to prevent reinfection. The authors add that the lesions should have entirely disappeared by the third day.

## Obstetrics and Gynaecology

523. Treatment of Placenta Praevia.

523. Treatment of Placenta Praevia.  
A H BILL (*Amer Journ Obstet and Gynecol*, October 19-7 p 523) asserts that although the abandonment of accouchement force has brought about an improved prognosis in cases of placenta praevia, the average maternal mortality — 10 percent or more in all cases and about 25 percent in central placenta praevia — has become but little reduced during the last twenty years. He believes that better results will be obtained when (1) recourse is had more frequently to blood transfusion before delivery and (2) Caesarean section is realized to be the least traumatizing way of ending labor in cases in which the os is not dilated. By prophylactic transfusions and by Caesarean sections there is diminution of the risk of severe post partum bleeding from the placenta site. This is the most common cause of death in placenta praevia and occurs in cases in which delivery by bag and forceps or by bag and version has been uncomplicated by hemorrhage and in which the cervix has been proved intact. In the author's practice no vaginal examinations are made in ante partum hemorrhage but the diagnosis is based on the history, the appearance of bleeding, abdominal palpation and auscultation and rectal examination. The detection of marginal as distinct from central placenta praevia is frequently deferred until operation. Blood transfusion is performed in about one fifth of cases, frequently at the same time as the Caesarean section. No patient is delivered who has a red blood cell count of less than three million or a blood pressure of less than 90 mm systolic and 60 mm diastolic until transfusion has been given. Bill publishes a series of 56 cases of placenta praevia with a maternal mortality of one and a fetal mortality of 13, in the case of the patient who died the husband did not consent to transfusion or section until she was moribund.

**529 Premature Rupture of the Membranes**

A. MAYER (*Zentralbl. f. Gynäk.*, September 17th, 1927, p. 2429) states that in recent years it has become increasingly frequent to find the commencement of labour marked by rupture of the membranes instead of painful contractions of the uterus, several days may lapse before pains are felt. He does not approve of the advice, formerly given, to accelerate delivery in cases of premature rupture of the membranes by introduction of a dilating bag and version, such measures facilitate rather than prevent infection, of which the danger from early rupture of the membranes has, he thinks, been exaggerated. In the great majority of cases expectant treatment is followed by spontaneous delivery and a normal puerperium. Mayer advises that after premature rupture of the membranes patients should be admitted without vaginal examination into an obstetric institution, where the labour can be conducted without haste in conditions of asepsis.

530. E. FREY (*ibid.*, September 23rd, 1927, p. 2294) states that the frequency of premature rupture of the membranes is so considerable that this condition should be regarded as a variation of physiological labour. In a series of 500 births he found that in about one in four labours in primiparae and one in three in multiparae early rupture of the membranes occurred, to be followed usually by the appearance of uterine contractions fourteen hours later in primiparae and twenty hours later in multiparae. In contrast with the usual reports the author has found that premature rupture of the membranes is not associated with an increase in the time elapsing between onset of pains and delivery of the foetus, or with increase in the number of pains, on the contrary, he has discovered that both are diminished by about one third. Frey remarks that it would be erroneous to assume from these data that artificial rupture of the membranes exerts any accelerating influence on labour if performed before the end of the first stage. Apart from abnormal rupture of the membranes Frey gives unusually small figures for the average duration of normal labour—namely, thirteen hours in primiparae, and seven and a quarter hours in multiparae with normal pelvic dimensions.

**531 The Menstrual Cycle in Relation to Ovulation and Conception**

S. A. ASDELL (*Journ. Amer. Med. Assoc.*, August 13th, 1927, p. 509), as the result of the investigation of patients at operations and necropsies and of study of the literature, finds that fertility in women is highest in the early part of the menstrual cycle, and that there is a very rapid fall from the sixteenth to the twentieth day. He has obtained no substantial evidence that any period of complete sterility exists. While the time from ovulation to menstruation is relatively invariable, that from menstruation to the next appearance of the ovum shows considerable variation. Consequently the corpus luteum influences markedly the time of onset of menstruation, but the period required for the development of the resting follicle to the stage necessary for ovulation varies considerably with the individual. This explains the variation in menstruation and conception dates. The author believes that the sex ratio is not affected by the date of conception.

## Pathology.

**532 Extramedullary Haematopoiesis in Anaemia**

D. BRANNAN (*Bull. Johns Hopkins Hosp.*, August, 1927, p. 104) reviews the literature concerning extramedullary haematopoiesis in infantile and adult anaemias, and reports a case of large tumours of haematopoietic tissue occurring in an anaemic infant, contrasting it with an adult anaemic case of extramedullary blood formation. The infant, 7½ months old, presented an anaemia with splenomegaly and an enlarged liver associated with rickets and malnutrition. The blood picture showed a great number of normoblasts and an increase in early myeloid cells. The erythrocytic nuclei were very irregularly lobed, and occasional cells were seen in mitosis. Because of the lobed nuclei and the large size and unusual staining of the erythrocytes (diffuse basophilia and pallor being marked) some of these resembled leucocytes. Megakaryoblasts were not abundant, and the platelets were greatly reduced. Lymphocytes were easily identified, and a low percentage of eosinophils and myelocytes was noteworthy. Important post mortem findings were red growths filling the hilus of the kidneys, and abundant red tissue, composed of all the elements of hyperplastic bone marrow with a great predominance of erythrocytic cells, covering the full cochlear. The red lymph nodes and thymus microscopically presented a marked haematopoiesis. The bone marrow also revealed great erythrocytic activity. The red colour found in the renal masses and elsewhere was due to the rich haemoglobin

content of the cells. The spleen was considerably enlarged and fibrosed, and, with the liver, gave little evidence of blood formation. Brannan has also noted haematopoiesis in the broad ligaments of three other infants, and in the breasts of a fourth. In the adult case, a female, in which haemorrhage and sepsis were obvious etiological factors, there was very definite evidence of blood formation in the liver, spleen, broad ligaments, and parametria, the lymph nodes also showing a slight leucopoiesis. Brannan concludes that extramedullary haematopoiesis is fairly common in certain anaemias of infancy and childhood, the growths occurring particularly in the kidneys. Blood formation outside the bone marrow is occasionally seen in the severe anaemias of adults, even in the presence of a hyperplastic marrow, and may be observed in the broad ligaments and in organizing thrombi, as well as in the usual sites. It may also be seen in the broad ligaments and breasts of infants under apparently normal conditions. Extramedullary haematopoiesis is to be regarded as a compensatory reaction, and appears to start in foci of type cells, either erythropoiesis or leucopoiesis, which substantiates previous observations regarding blood formation in the bone marrow.

**533 Phosphorus Metabolism in Mental Disease**

T. KÖRA (*Japanese Journ. of Med. Sci.*, June 30th, 1927, p. 53) estimated the total phosphorus content of the blood serum by Klemm's modification of Bloch's nephelometric method in a number of healthy adults and mental patients suffering from various disorders. The blood was in each case collected before breakfast with the subject fasting, special care being taken to avoid mental or physical overwork. The average (35.634 mg.) total phosphorus per 100 c.c. serum in the healthy female was 4.159 mg. higher than in the male. The effects of night work and of examinations on the blood of some of the nursing staff were also studied, and both these factors were found markedly to increase the phosphorus content in almost every case. In patients with general paralysis the phosphorus content was greatly increased before malaria therapy, less so after, the greater the degree of recovery the more closely did the value approach the normal average. In katatonic stupor and agitation it was also raised, falling again during remissions. In melancholia the phosphorus figures varied greatly, being high during agitation and insomnia and low in cases of absent-mindedness and indifference. In manic and melancholic patients the phosphorus content was also raised, while in epileptics it was much increased for a few hours after an attack. The effect of luminal in a number of mental patients was to lower the average phosphorus content of the blood by 6.379 mg. As a result of his observations on pathological cases Köra considers that the increase in phosphorus content is due to degeneration of brain cells and is to some extent proportional to the severity of the clinical symptoms.

**534 The Resting Minute Volume of the Heart during Fever**

H. BJERLÖW and G. LILJSTRAND (*Acta Med. Scand.*, October 8th, 1927, p. 5) assert that, while the correlation between fever and pulse rate has long been recognized, and also the effect of fever on the heart itself, especially with regard to its functional capacity, little is known concerning the amount of work that the heart has to perform during fever and of the factors determining the work of the heart—that is, the minute volume of the heart. Opinions vary as to whether during fever the general blood flow becomes accelerated or not. Liebermeister refers to the great difference in temperature between the periphery and the interior of the body in cases with high fever, and thinks that this difference may be explained as the result of a slower circulation through the periphery. Stewart found that in fever the blood flow in the feet never exceeded and was usually much below the normal. He suggests that during fever the vasoconstrictor mechanism of the peripheral parts, especially of the skin, is abnormally excited, and that this is a compensatory arrangement securing an increased blood flow for the organs mainly suffering from the infective process. On this hypothesis fever is a secondary phenomenon. The present authors studied the effect of fever on the minute volume of the heart in cases in which fluctuations of recurrent fever had been given for various nervous diseases. It was found that the standard metabolism showed a typical increase with the rise of temperature. The utilization of the oxygen of the blood remained constant during normal and elevated rectal temperatures. There was thus during fever a rise in the minute volume of the heart in direct proportion to the increase in oxygen consumption. The output per beat remained unaltered or was diminished. The blood pressure being somewhat higher during fever than at the normal body temperature, the work of the heart must rise during fever slightly more than in proportion to the standard metabolism.

## Medicine.

### 535. Treatment of Pulmonary Abscess by Artificial Pneumothorax

E. BATTONI (*Il Policlinico*, Ser. Prat. October 10th, 1927) reports a case of pulmonary abscess cured by therapeutic pneumothorax. A brass-worker, aged 54, suffered from frequent shivering and intermittent fever, with copious purulent expectoration and attacks of vomiting. The sputum contained pyogenic bacteria in large quantities, pus cells, and elastic fibres. The physical signs and radioscopic examination indicated the absence of the upper lobe of the right lung. For three weeks the patient was treated with terebene inhalations without any improvement. A pneumothorax was then induced, ultragen being substituted for air with refillings at intervals of ten months. At first the refills were given every fifth day for four injections, the subsequent five injections being given every tenth day after which the patient was sent out of hospital in good condition. He continued to attend as an out-patient having four injections at intervals of ten days between each, then one was given every three weeks, and after six of these three final injections were made with intervening periods of four weeks each. Altogether he had 22 injections of ultragen into the pleural cavity with no mishap. From the 11th day the patient improved and after the 14th injection he had no more fever and had gained 20 lb. in weight. The man was able to resume his employment and remained perfectly well up to the time of reporting. The author discusses in detail the etiology of this condition, and believes that artificial pneumothorax will be found to be a valuable form of treatment.

### 536. Cardiac Disturbance in Thyroid Disease

J. V. READ (*Journal Amer. Med. Assoc.* August 13th, 1927) discusses cardiac disturbances traceable directly to pathological changes in the thyroid gland as those due to hypothyroidism, those secondary to obstructed respiration, and those occurring in hyperthyroidism. Marked congestive failure is occasionally seen in myxoedematous patients who do not respond to rest and digitalis but improve when thyroid extract is given. Read states that this treatment should be applied carefully and attention should be paid to the ability of the heart to meet the demand for the increased blood flow which accompanies the consequent raising of the metabolic rate. He believes that the incidence of cardiac complications in hyperthyroidism is less than is generally assumed; dyspnoea, tachycardia, and palpitation not being necessary evidence of cardiac disease, but rather manifestations of thyrotoxicosis. It has been estimated that over half the patients presenting cardiac symptoms have no demonstrable enlargement of the heart. Read mentions two theories of pathogenesis—namely that a thyrotoxin acts directly on the heart muscle and that cardiac fatigue occurs. He gives reasons for believing that the second is the more probable and emphasizes the importance of rest as a factor in treatment. Sedatives may also be of value and digitalis should be given in decompensation especially if auricular fibrillation is present. He adds that quinine seems to have a special value in the treatment of the cardiac manifestations of hyperthyroidism while quinine frequently reduces the rapid and heavy beating of a regular heart when the pulse rate is out of proportion to the metabolic rate.

### 537. Coincident Diphtheria and Typhoid Fever

According to A. J. P. HAYE (*Th. de Paris* 1927 No. 417) typho-diphtheria or the association of typhoid fever and diphtheria which was first described by Osmond in 1859 and used to be regarded as a rare occurrence was fairly frequent during the war. Among 4,000 typhoid patients under Joltrain's care in the course of eight months during 1915 there were 120 cases of this combination and among 4,197 typhoid patients under Rathery's care in the same year 109 cases. Since the war the disease has been rare but HAYE records a case in a girl aged 14 which occurred in the Hôpital des Enfants Malades, Paris, in January 1927. Typho-diphtheria is essentially a hospital disease and is due to contamination by patients and carriers. It begins with the typhoid fever when this infection is at its height and the patient, months afterwards, is peculiarly characterized by general symptoms caused by the association of diphtherial toxinæmia and typhoid septicæmia. The symptoms and physical signs are often ill marked. The complications are

those of typhoid fever and diphtheria. Sudden death is liable to occur. Two forms of exchyma may be met with—namely, an acute form which is rapidly fatal and a chronic form in which several months may elapse before recovery. The diagnosis is fairly easy if the possibility of the coincidence of the two diseases is borne in mind. The prognosis is grave and depends on the stage at which treatment is started. Early intense and prolonged administration of diphtheria antitoxin is required in addition to the ordinary treatment of typhoid fever.

### 538. Etiology of Influenza in Children

C. LACOSTE (*Il Clin. Pediat.* September 1927, p. 659) states that during an epidemic of influenza at Milan in the autumn and winter of 1925-26 in which a large number of children were attacked he carried out investigations for Pfeiffer's bacillus with the following results. The organism was found in direct smears of the pharyngeal mucus or expectoration in 3 out of 15 children with uncomplicated attacks in 3 out of 10 with lung complications in 1 out of 6 convalescents and in 1 out of 3 cases of suppurative arthritis. It was recovered from cultures in 20 per cent of the specimens of pharyngeal mucus in 4 out of 12 specimens of urine, and in 1 case of suppurative arthritis in association with the pneumococci. Blood cultures were constantly negative for this organism. Among 14 cases examined the pneumococcus being found twice and an organism resembling Pfeiffer's bacillus once. A similar result was obtained from cultivation of the cerebrospinal fluid, the pneumococcus being found in only one case in which well marked changes were present in the fluid. In 13 out of 21 cases tested specific agglutinins were found in dilutions ranging from 1 in 10 to 1 in 2.0 both in the acute stage and in convalescence. Only a very slight disturbance was produced in animals by injection of various strains of Pfeiffer's bacillus. No definite conclusions therefore could be drawn as to the causal agency of Pfeiffer's bacillus in the epidemic.

## Surgery

### 539. Periarterial Sympathectomy

R. LEFICHOIE (*Presse. M. I.* October 19th, 1927, p. 1267) is of the opinion that periarterial sympathectomy does not act by cutting off the excitomotor fibres of the sympathetic nervous system. Its effect depends upon the sensory nerves which bring about a vaso-dilatation more marked in the affected limb. It appears that stripping of the vessel for a considerable distance is necessary for success. When the walls of the artery are degenerated they are exposed to the risk of perforation or even rupture which endangers the vitality of the affected limb or even the life of the patient. The operation therefore is not without risk. The operation of periarterial sympathectomy gives immediate and often beneficial results but good ultimate results are rare. It is doubtful if many of these can be attributed to the operation alone. It has been proved that operations are simple and less risky on the sensory nerves have proved just as satisfactory whilst physiotherapeutic methods have also yielded equally good results without exposing the patient to any risk.

### 540. Rare Precancerous Processes in the Tongue.

S. VOGELER MOER (*An. del Hosp. de la Sta. Cruz y S. Pablo*, September 15th, 1927, p. 254) describes the following rare precancerous processes in the tongue. (1) Acute granular papillitis or sandy tongue. In this condition the whole (or the dorsal aspect) of the tongue appears to be sprinkled over with a large number of small red hemispherical projections ranging in size from a heap of dust to a small pin's head. The process lasts only one or two days and then disappears leaving a condition of redness and irritability of the tongue which persists for about a week. The sudden onset and disappearance and the exclusive localization of the lesions to the lingual mucosa indicate a local infection by streptococci or staphylococci or a virus. In treating the condition care should be taken to avoid all applications which have an irritating or caustic action. The best results were obtained by the use of 1 in 1000 solution of zinc sulphate or 1 in 15 watery solution of neosalvarsan. (2) Chronic granular papillitis. In this condition the dorsal aspect of the tongue shows bright red fine granulations 1 to 2 mm thick which readily bleed on being scraped. Some of

the granulations disappear as the result of exfoliative glossitis, while others become enlarged and unite with one another, forming a mulberry shaped growth resembling an epithelioma. Unless treated vigorously the condition undergoes a malignant change in a few months. Treatment should consist in radium puncture or electro coagulation. (3) Flammiform granular glossitis which is merely a more advanced stage of the second form. The granulations secrete a sero haemorrhagic fluid due to friction against the upper teeth, and an epitheliomatous change is facilitated. The treatment is the same as in the previous form, but should be carried out more energetically.

#### 541 Tuberculosis of the Knee-Joint

M S HENDERSON and H J FORTIN (*Journ Bone and Joint Surg*, October, 1927, p 701) consider that tuberculosis of the knee joint in the adult usually warrants resection. A good result rarely follows conservative treatment in such cases, and much time is wasted. The authors record 211 cases of resection, with end results in 194. There was no operative mortality. In 171 patients firm bony union was secured with good function, union failed in 22 cases. A bone graft was used in four of these, and union then resulted. Seventeen patients have since died from extension of the tuberculosis, these lived an average of four and a half years after the operation, which relieves the patient of a painful and distressing condition and restores him practically to full activity, so that he can again take a place in industrial life. The average age of the patients was 29 years. All these cases appear to be secondary to a focus elsewhere in the body, and the joint infection occurs by the blood stream. A history of trauma was noted in a few cases.

#### 542 Staphylococcal Septicaemia

J ARIS (*Rev med de Barcelona*, September, 1927, p 239), who records five illustrative cases in patients aged from 18 to 40, three of which were fatal, states that boils of the face, especially on the upper lip, alae nasi, cheek, and chin, are the chief cause of septicaemia. This form of septicaemia is due to a superinfection rather than to an auto infection. A careful study of the blood cultures will show whether the staphylococcus is alone responsible or if it is associated with the streptococcus. Early diagnosis is essential, and is founded on the rapid swelling of the tissue surrounding the boil, the lancinating and throbbing character of the pain, shivering, and sudden development of a high temperature. The use of the knife should be avoided, since in the absence of pus it opens up channels to microbial invasion. Deep linear canterizations should be made on one or both sides according to the case. Fixation abscesses have proved useful in treatment.

#### 543 Treatment of Coxa Vara

H JUDET (*Bull et Mem Soc de Chir de Paris*, Tomo XIX, No 12, 1927, p 550) describes the methods he has adopted in treating cases of coxa vara in young adults. In the first place he corrects the malposition of the limb—that is to say, the external rotation and the adduction. This is always possible under general anaesthesia, and he fixes the leg in moderate abduction and slight internal rotation. The limb is best held in this position by means of plaster of Paris, as advocated by Whitmann in fractures of the neck of the femur. This is continued for two months, when the plaster is removed. The second stage of the treatment then consists in fixing the patient with a special type of splint extending from the pelvis to the foot. This is hinged at the hip, knee, and ankle, and the patient is enabled to walk in it. At the age of 18 to 20 years the neck of the femur is firmly consolidated and the ultimate result is satisfactory, and often perfect. In malunited cases a cuneiform osteotomy below the great trochanter, followed by abduction of the limb in plaster, re-establishes the normal angle of the neck of the femur.

## Therapeutics.

#### 544 Milk Injections in Protein Therapy

F H RODIN and R W MCBRIDE (*Amer Journ Med Sci*, October, 1927, p 511) discuss the effects on the leucocytes and the temperature of the use of milk injections as a form of non specific protein therapy. In their experiments the milk was boiled for three minutes, this being long enough to destroy bacterial contamination, and not long enough to inactivate the active component. Amounts of 15 c.c.m. were usually administered, the injections being made deeply into the buttocks. If the treatment was repeated, this was done after forty eight hours, and again after a like interval. Blood counts were made from a few minutes to six hours before the injection, and again from six to twelve hours after it. The temperature was recorded every two hours for three to five

days. A chill of varying intensity, nausea, and vomiting were observed in some cases, but otherwise no ill effects followed the injections. Of 26 patients receiving fifty injections only one patient, who had a normal temperature before an injection, failed to show a rise afterwards, the temperature being 2° F. Leucocytosis occurred in 24 patients and of these 21 showed an increase in the polymorphonuclears and a decrease in the lymphocytes. The leucocytic increase averaged 53 per cent, the polymorphonuclears 13 per cent and the lymphocytic decrease 11.8 per cent. The elevation of temperature, the increase in the leucocytes, and the percentage of the polymorphonuclears were roughly parallel to each other. The authors maintain that the persistence of the pyrexia for about sixty hours and the leucocytosis from three to five days, added to the fact that the reactions to such injections are very mild as compared with other kinds of non specific protein therapy, justifies the use of milk for such treatment. For repeated injections it should be given every third or fourth day.

#### 545 Antitoxin Treatment of Erysipelas

D SYMMERS and K M LEWIS (*Journ Amer Med Assn*, September 10th, 1927, p 830), who record their observations on 131 patients at the Bellevue Hospital, New York state that the results of the antitoxin treatment of erysipelas are commensurate with those obtained in the treatment of diphtheria. In the present series there were only 7 deaths, a mortality of 5.2 per cent, whereas in a series of 107 cases treated without antitoxin in the corresponding season of the previous year the mortality was 11.2 per cent. The antitoxin treatment, however, does not confer immunity, and recurrent attacks occur as often as before, nor does it appear to diminish the frequency of complications, such as abscesses. Facial erysipelas responded more readily to antitoxin treatment than erysipelas of the trunk and extremities. The best method of administering antitoxin was found to be the intramuscular route. Intravenous injection, according to the authors, is dangerous, and should only be used in desperate circumstances.

#### 546 Chaulmoogra Oil in Ozaena

G CILIGERO (*Rassegna Inter di Clin e Terap*, August 1927, p 537) has treated ten typical cases of ozaena by the application of chaulmoogra oil with encouraging results. He uses at first a 30 per cent ointment and continues with a mixture of equal parts of the oil and vaseline. In some cases he has used the pure oil to test the degree of tolerance of the mucosa, and he has also given injections of the oil. No other treatment was used simultaneously. After the second or third application the fetor diminished, and in a couple of months the crusts disappeared, one month later the mucous membrane had lost its dry, atrophic appearance and seemed practically normal. So far the patients have remained free from recurrence, but the author, realizing the temporary nature of the relief which follows various methods of treatment in this disease, is still keeping these patients under observation. He adds that no treatment previously tried has given such excellent results.

#### 547 Nitro-hydrochloric Acid in the Treatment of Hay Fever

ADVOCATING the administration of nitro hydrochloric acid in the treatment of hay fever H BECKMAN (*Amer Journ Med Sci*, October, 1927, p 525) reports 17 cases showing 100 per cent of symptomatic cures. All these patients, who had previously received pollen or topical treatment without benefit, were rendered practically symptomless by the acid, and have obtained relief each year in which it was used. They were of both sexes, and their ages ranged from 8 to 72 years. Beckman prescribes the acid in the following manner. Nitro hydrochloric acid (not the dilute, but the strong form of the United States Pharmacopoeia) 4½ drachms, distilled water to 4 oz., one teaspoonful of this is taken in two thirds of a glass of water, followed by another glass of water, after each meal and again on retiring, as near midnight as possible. This mixture is pleasantly acid and not corrosive to the tissues. Beckman states that even such large doses of the acid can be considered as dangerous. Emphasis is laid on the importance of the midnight dose.

#### 548 Manganese Salts in Hypertension

G L PIOTROWSKI (*Med Journ and Record*, October 19, 1927, p 490) casts doubt on the value of manganese salts as therapeutics. He used a combination of the salts with thyroid extract in ten cases of hypertension. In nine of these there was hypertension with a marked arterio-sclerosis, and diminution of the specific gravity of the urine, in the last of these there was also retention of urea in the blood. Diminution in the excretion of phenolphthalein. The tenth patient had hyperpnea. Piotrowski treated

in the administration of one eighth of a grain of potassium permanganate and 2 grains of thyroid extract in a cyclic. This medication was continued for three weeks without any lowering effect on the blood pressure. The author describes experiments in which guinea pigs were injected with tubercle bacilli of the human type and treated by injections of a chemical compound of iodine and potassium with mannose. No evidence was obtained that in man, as in guinea pigs, the therapeutic value.

#### 549 Exophthalmic Goitre Treated by Increasing Doses of Iodine

L. DUTREBANDI and A. L. MORT (*Bruzelles Medical*, October 16th, 1927 p 1634) report a method of treating Basedow's disease by progressive doses of Lugol's solution of iodine. They state that although it is agreed that iodine administration is valuable during the crises of exophthalmic goitre and in the prevention of post-operative hyperthyroidism, yet up to the present the benefit has been considered to be only transient, and its principal use has been to reduce post-operative mortality. They think that this opinion should be revised. Prolonged treatment by iodine should be limited to cases of pure exophthalmic goitre, excluding all with adenomatous nodules. At the commencement of treatment a daily dose is given of 20 minims of the following solution: iodine 10 grains, potassium iodide 20 grains, water 100 c.c. They progressively increase the dose to the basal metabolic index as an index. They claim that in 80 per cent of their cases a rise in metabolism has been overcome in this way. Although it is impossible to increase the dose of iodine indefinitely, the authors state that certain of their patients have been taking with benefit 100 to 150 drops of the solution daily for several months. Compared with the uncertainty of permanent benefit which follows the use of the thyroid arteries radiotherapy, or thyroidectomy, the authors claim that this intensive medication with iodine is relatively reliable. The explanation offered is that exophthalmic goitre is a local affection determined by general endocrine factors. Iodine lowers the metabolic rate and thus causes disappearance of the symptoms. The method it is added has at least the merit of being an ambulatory treatment and of placing the whole organism in a generally favourable condition for further intervention, should this prove necessary.

### Dermatology.

#### 550 Paronychia due to *Odium albicans*

H. LACOMBE (*Brit. Journ. of Derm. and Syph.* October 1927 p 294) describes two cases of paronychia due to *Odium albicans* and refers to the literature of this rare condition. His first patient was a woman aged 65 in good circumstances for ten years. She had had repeated attacks of inflammation of the nail folds of various fingers, the thumb-nail being involved. The intervals between the attacks varied from weeks to months. At the onset a red spot appeared at the nail fold and yellow pus developed in it. Later there came the characteristic bolster-like swelling of the fold described by Shelmire. The nail as a rule became loose and was shed. The new nail was normal in appearance except for longitudinal striation. The amount of pain varied but was never severe. The pathological examination showed that the discharge was not pus in the strict sense but among the epithelial cells were mycelial threads. *Staphylococcus albus* was also present. The mycelium on culture presented the characters of *Odium albicans*. The second patient was a sister of the first.

#### 551 Actinotherapy in Dermatology

A. BODART (*Bruzelles Medical*, October 2nd 1927 p 1556) asserts that ultra violet rays exert a triple action: (1) bactericidal acting chiefly on the surface and with slight penetrating power; (2) stimulating, exciting the growth bromatopoiesis and cicatrization of tissues; and (3) external resensitization when strong doses are used. Quartz lamps were usually employed by Bodart. Actinotherapy can be applied either simply alone in conjunction with other physical agents or with chemical photosensibilizing agents and the method of application is briefly described. Physical agents notably infra red rays are being more and more used in association with ultra violet ones as they have a moderating action on active erythema and radio dermatitis. The benefits arising from the combination of these two agents are striking, as seen in surgical tuberculosis. The chief indications for the use of ultra violet rays are the pyodermites cutaneous, tuberculous, ulcers cutaneous mycoses, chronic eczemas, certain parakeratosis and alopecias. Their use is contraindicated in acute febrile eczema, radio dermatitis, actinic xeroderma pigmentosum, and in all cases of hyperchromia such as

leucoderma and chloasma. In the last ultra red rays are best employed. The sources of ultra violet rays do not only produce these, but also a series of radiations which in quartz mercury lamps, correspond to the spectrum of mercury vapour. Wood has constructed a screen of very deeply coloured glass with a metal oxide base which is very slightly permeable to blue and violet rays but markedly to ultra violet ones. With this lamp healthy skin has a greenish blue fluorescence, the nails are pearly, ordinary hairs appear black, while those affected with trichophytosis give a greenish blue. The parakeratosis appears very pale and the pruritus premonitory to eczema gives an orange tint. Bodart believes that the use of ultra violet rays will become more and more general, and that Wood's lamp will prove to be an indispensable auxiliary.

#### 552 Dermatoses due to Light Stimulation

S. S. GREENBAUM (*Amer. Journ. Dis. Child* July 1927, p 81) draws attention to the severe reactions which though rare may follow on exposure to the rays at the short end of the visible and at the long end of the ultra violet light. In certain circumstances there may be an increase in the amount of the normal photosensitive substances in the tissues or the development in vivo of a new one. Various workers have suggested that these substances which absorb wave lengths characteristic of them are the porphyrins, the aromatic amino acids of the proteins and bacterial toxins acting on the epidermal cells. The author divides specific cutaneous sunlight reactions into two groups according as they are congenital or acquired. Among the congenital reactions he mentions hydroa vacciniforme (Bazin) a vesicle hallow eruption appearing twelve to twenty four hours after exposure to sunlight. It is first detected when the child is three or four years old and immunity is gradually acquired. Another congenital reaction is xeroderma pigmentosum which begins at the age of 1 or 2 as a dry and rough appearance of the exposed skin. Dark pigmented spots and white atrophic areas develop later together with telangiectases and leucoderma. The latter undergoing malignant degeneration death usually occurs before the twelfth year from metastases. In the acquired group are cases following genuine saturation intravenous injections of mercury bismuth applications of crude coal tar fairly complete saturation with x-rays and mercurial dermatitis. Severe atonic effects have also been observed in lupus erythematosus, some eczema, various and Addison's disease. Baier and his co-workers describe a primary dermatitis in this group where the clinical picture following exposure is an eczema not sunburn. Greenbaum emphasizes the importance particularly in infants of a preliminary test before light treatment in order to determine the degree of tolerance of sensitivity present.

#### 553 Skin Manifestations of Tularemia

E. W. NETHERTON (*Arch. Derm. and Syph.* August 1927 p 170) who reports an illustrative case with a histological report of the lesions, states that the cutaneous lesions of tularemia may be divided into (1) subcutaneous nodules which simulate those seen in sporotrichosis and like them may suppurate and rupture their situation being along the lymphatics which drain the primary lesions; (2) erythematous papules and plaques which follow exacerbation or relapse of the systemic symptoms. Among the rarer skin manifestations of tularemia are herpes and hyperaesthesia which may be either toxic or infectious, jaundice due to damage to the liver and aene. In Netherton's case which occurred in a woman aged 34 the eruption presented the appearance of erythema multiforme.

### Obstetrics and Gynaecology

#### 554 Induction of Labour for Disproportion between Foetus and Pelvis

BROUHA (*Gynecol. et Obstet.*, September 1927 p 205) discusses the induction of premature labour when the foetus and pelvis are of disproportionate size. The great drawback of induction which has the small maternal mortality of 1 per cent or less is the fact that from 5 to 16 per cent of foetuses are born dead and from 6 to 30 per cent of the live born premature foetuses fail to attain the age of 1 year. When the foetus to pelvic disproportion is due to the size of the foetus this drawback is less significant than when it is due to pelvic contraction in cases when one or more abnormally large babies have previously perished during labour, induction is advisable during the last weeks of pregnancy if the state of the cervix and the pre-natal are favourable. In a primipara with large foetus, Brouha prefers the test of labour pain to an induction. In cases of contracted pelvis the one of treatment lies chiefly between premature induction of labour

and Caesarean section. The foetal mortality of the latter is much less, and when allowance is made for the fact that in a large number of cases (70 per cent according to figures from the Tarnier Clinic) in which a probable Caesarean section has been contemplated a "test of labour" leads to spontaneous delivery, the comparable maternal mortalities of the two are about equal. Accordingly the smaller foetal mortality inclines the balance in favour of Caesarean section, of which the maternal mortality will probably be further diminished in the future with improvement of technique. Pelvimetry has improved, but the force of the uterine contractions and the malleability of the foetal head are factors which it is impossible to estimate in advance, so that in the great majority of cases of moderate pelvic contraction Brouha believes that the correct treatment is to watch labour carefully at term, performing Caesarean section by a low uterine incision if it becomes evident that natural forces will not suffice. The low operation, by diminishing the risk of infection, has made the "test of labour" more safe.

#### 555 Inflammation of the Bladder Simulating Neoplasm

J J JOLLSON and W L LOWER (*Surg., Gynecol. and Obstet.*, October, 1927, p 417) report three cases in which inflammatory lesions of the female bladder so closely simulated a true neoplasm as to cause difficulty in diagnosis. In the first, a woman aged 30, a localized tuberculous lesion of the bladder wall at the left ureteral opening resulted from a tuberculous kidney without the usual generalized cystitis, the possible explanation being that the tuberculoma, by occluding the ureteral opening, prevented the entrance of infected urine. This view is supported by the facts that the bladder urine was free from pus until after the removal of the tuberculoma, that the right kidney was hyperactive, and that a fortnight after operation the left kidney was functioning so poorly as not to excrete any indigo carmine. In the other two cases inflammatory reactions were set up in the bladder wall by a primary focus of inflammation in the adnexa uteri. The main symptoms in all three cases were dysuria, frequency, and nocturia, with pyuria in two and a history of haematuria in one. The authors consider that while the diagnosis from a true neoplasm may be difficult, these inflammatory tumours show certain characteristics which aid in differentiation. Instead of having a definite papillary appearance they present fairly large club shaped villi, some of which may appear cystic or translucent, they are usually rosier in colour and show no sign of invasion of the surrounding mucosa. Owing to this difficulty in diagnosis the possibility of such a lesion should always be borne in mind in women, in cases of doubt an exploratory operation may be advisable.

#### 556 Temporary Sterilization by Insulin

E VOGT (*Zentralbl. f. Gynak.*, September 17th, 1927, p 2436) has found that two or three daily injections of insulin spread over four weeks destroyed sexual desire in female rabbits, and microscopic examination of their ovaries showed an abnormal sparseness of ripening and ripened follicles. Riddle, by administration of small doses of insulin, has been able to prevent ovulation in buns. Previous reports have been published on experimental hormonal sterilization by transplantation of ovaries from pregnant animals, by injection of extracts of such ovaries, and by injection of placental extracts. Dittler, by intravenous injection of spermatic fluid, induced temporary sterility lasting four months in rabbits. Vogt thinks that such experiments may find an important practical application in the human subject. Temporary sterilization, for example, in cases of tuberculosis, might be more conveniently and safely induced by insulin treatment than by operation or small x-ray applications. That in the reverse fashion the ovarian internal secretion may influence that of the pancreas is suggested by an observation of KUPFERBLERG (*ibid.*, p 2438), who found that after applications of radium for carcinoma of the uterus a patient became cured of diabetes, and has since treated several cases of diabetes by introduction of radium into the vagina. Diabetes in a male is reported to have been influenced favourably by placing radium within the rectum.

## Pathology.

#### 557 Permeability of the Meninges to Antibodies

M CILCA, I BALTEANU, and L BALLET (*C. R. Soc. de Biologie*, October 21st, 1927, p 1122) have endeavoured to render the meninges permeable to antibodies. Previous work by one of the authors had shown that both complement and antibodies such as agglutinins, precipitins, and lysins were absent from the cerebrospinal fluid of patients whose blood contained them in large quantities, neither the onset of a chronic meningitis nor the artificial injection of physio-

logical saline solution into the spinal canal rendered the meninges permeable to these substances. In meningeal infections, such as tetanus and cerebrospinal fever, it is therefore necessary to introduce the antiserum directly into the spinal fluid. This method, however, is open to objections, if the serum treatment is continued for long, and phylaxis or serious meningitis may be set up. It would be of great advantage in these cases if the serum could be injected into the blood stream, and thence pass into the spinal fluid. The discovery that urotropine altered the permeability of the meninges to the virus of herpes led the authors to think that the intravenous injection of this drug might so affect the meninges as to allow of the passage of antibodies from the blood stream into the spinal fluid. In the first series of experiments they injected 40,000 to 59,000 units of diphtheria antitoxin into the subcutaneous tissue, and withdrew samples of the blood and the cerebrospinal fluid from seven to forty-eight hours later. The presence of antitoxin was tested for by Romei's intracutaneous method on guinea pigs or rabbits. In two general paralytic patients and one convalescent from encephalitis tested in this way they failed to detect the least trace of antitoxin in the spinal fluid, even though 0.025 c.c. of blood serum neutralized completely 160 doses of toxin. In the second series of experiments, performed on three patients with, respectively, dementia praecox, epilepsy, and encephalitis, the antiserum was injected as before, and, in addition, large doses of urotropine—12 to 63.5 grams daily—were given intravenously, but not a trace of antitoxin could be detected in the spinal fluid. If, however, the same antiserum was injected into the spinal fluid, it passed in less than seven hours into the blood, and after thirty-eight hours no trace of antitoxin was left in the spinal fluid. The authors conclude that in man neither chronic meningeal inflammation nor the injection of urotropine renders the meninges permeable to diphtheria antitoxin.

#### 558

#### Isolation of the Bacteriophage

A F DE GROAT (*Journal of Immunol.*, September, 1927, p 175) maintains that for proper study of the bacteriophage it should be employed in a pure condition. To free it from the proteins of the culture medium and from the products of bacterial lysis he has devised a method of adsorbing it on to the bodies of living bacteria, and subsequently liberating it from these by a process of heat, washing, and filtration. Briefly, his technique is as follows. Working with *B. coli* and an anti-*coli* phage he mixes about equal quantities of a thick *coli* suspension and a *B. coli* bacteriophage filtrate, and leaves the mixture in the refrigerator three hours, the organisms are then killed by heat in a 60°C water bath for fifteen minutes. After cooling, the mixture is centrifuged at high speed for twenty minutes, the supernatant fluid is discarded, and the deposited organisms are washed with a large quantity of saline solution and suspended in a smaller quantity of distilled water. After twenty-four hours in the incubator the suspension is filtered through a Berkefeld candle, and the resulting filtrate is preserved as pure bacteriophage. Tests for protein in this purified filtrate are entirely negative. Experiment showed that the bacteriophage could not be adsorbed on to the bodies of dead bacilli. The success of the technique described seems to indicate that the bacteriophage can easily be detached from the bodies of dead bacilli on to which it had been adsorbed while they were still alive.

#### 559

#### The Oxydase Reaction and Menstruation

V COSTABILE (*Il Morgagni*, October 2nd, 1927, p 156), from a study of the oxydase reaction—that is, the formation of dark blue granulations in the leucocytes when treated with alpha naphthol and dimethyl paraphenylenediamine—in 20 cases of menstruation came to the following conclusions. The oxydases on the leucocytes increase during the menstrual flow, especially at its acme. In the premenstrual period of dysmenorrhoeic subjects the oxydase contents of the leucocytes is lower than in healthy women, but it increases at the height of menstruation. The increase of oxydases appears to be due to a greater activity of certain endocrine glands, especially the thyroid and ovary, at the menstrual period.

#### 560

#### Examination of the Cerebrospinal Fluid for Tubercle Bacilli

LANCELIN, BIDEAU, and DUBIFUILL (*C. R. Soc. de Biologie*, October 21st, 1927, p 1056) find that the best method of detecting tubercle bacilli in the cerebrospinal fluid is to allow the fluid to rest till a fibrinous clot forms. This is then removed by a platinum loop and spread on a slide. To free it from excess of fluid it is transferred to two or three moist slides in succession. When it has dried it is fixed and stained, a picric acid solution being used for counterstaining. The bacilli are caught up in the meshes of the clot, and can be found rapidly and in considerable numbers. This method has given nearly 100 per cent of successes.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 561 Chicken pox with Extension to Larynx

H M JARR (*Arch of Pediat*, September 1927 p 599) records the case of a girl, aged 11, who during a severe attack of chicken pox began to suffer from dysphagia and hoarseness. There were several vesicles on the anterior pillars and posterior pharyngeal wall. The larynx was generally reddened and congested, and on the left vocal cord remnants of two ruptured vesicles were seen. Both vocal cords were slightly rounded and oedematous. The throat symptoms lasted four days and disappeared on the fifth day. The dysphagia and cough persisted for three days and subsequent recovery was uneventful. Only two similar cases of laryngitis in chicken pox reported by Marfan and Hallé have been recorded one preceding and the other accompanying the eruption. Their first patient was a girl aged 3 who on the fourth day of chicken pox suffered from hoarseness and dyspnoea sufficiently severe to require tracheotomy to save her life. Their second case was in a baby, aged 9 months who showed swelling of the larynx with confluent patches. Death occurred on the seventh day of disease.

### 552 Oesophageal Stenosis of Aortic Origin

J A CANALEJAS (*Lancet* 1927 October 8th 1927 p 292) who records a fatal case, remarks that stenoses of the alimentary canal of aortic origin may be divided into two groups—namely, spasmodic and anatomical. A mild form of aortitis which does not exercise any pressure on the neighbouring organs may readily give rise to spasm of the larynx or oesophagus with all the symptoms of a neurotic condition such as intermittent inability to be induced by psychical factors, greater difficulty in swallowing liquids than solids, and disappearance of the obstruction under an anaesthetic, without however implying a favourable prognosis since it indicates an organic cause. In practice therefore, the spasmodic or functional nature of a dysphagia does not indicate a favourable prognosis in every case as the spasm may simply be the clinical manifestation of an incipient organic lesion. In the present case which occurred in a man aged 60 the dysphagia was no spasmodic but anatomical being due to direct compression of the oesophagus by the dilated aorta, although even in the most pronounced cases of this type the coexistence of a reflex spasmodic factor is possible. Vigorous antisyphilitic treatment is indicated in such cases.

### 553 Treatment of Migraine.

R BLAMONTIER (*Bull Soc de Ther* October 12th, 1927 p 225) inspired by the good results obtained in some cases of migraine in America by Vincent Lyon and in France by Chirry and Triboulet as the result of drainage of the gall bladder after intraductal injection of a concentrated solution of magnesium sulphate adopted this treatment in twenty two cases of typical severe migraine. The principal indications for the method were frequent and profuse vomiting during the attacks the presence of a large quantity of bile in the vomit and tenderness of the gall bladder. The only examples of cure or very marked improvement in Blamontier's series occurred in seven patients who had profuse bilious vomiting and tenderness of the gall bladder which disappeared after duodenal intubation eight patients who had only slight and mostly watery vomiting showed little improvement while the remaining seven who were rarely afflicted by nausea and vomiting were never bilious and had no tenderness of the gall bladder derived no benefit whatever from the treatment. Duodenal intubation was performed once a week and the duration of the treatment was from six weeks to two months on the average. Some showed improvement after the first intubation and others not till the fourth or fifth. Some patients had no recurrence of their symptoms while in others the migraine relapsed at varying intervals after the termination of treatment.

### 563 Striae Patellares following Typhoid Fever

J D ROLLESTON (*Clin Journ* October 25th 1927 p 476) who records an illustrative case, states that the condition of striae patellares which was first described by Reimier in his Paris thesis in 1860, is a localized form of the lesion which has received various names—such as striae atrophice striae cutis distensae striae albae variegates of the French and false Varicella of the Germans. It is met with after many infectious diseases, but is commonest after typhoid

fever. Striae patellares probably have a mechanical causation due partly to rapid growth of the skeleton because most of the cases have been in growing people and the condition may occur apart from any disease. They are commonest, however, after infectious diseases which increase growth, and are probably not due to a trophoecrosis as some writers have maintained. They possess some medico-legal interest as they constitute a means of identification. Rolleston's patient was a girl aged 14 in whom the striae were first noted on the forty third day of a typical attack of typhoid fever, three days before the evening temperature became finally normal. They consisted of symmetrical purplish transverse stripes on the skin about 1½ inches above the upper border of each patella numbering one on the left and three on the right and measuring 1 to 1½ inches in length. The skin was otherwise normal except for a slight degree of livedo reticularis of the lower limbs, and the knee joints were active. Rolleston has also recently seen a similar case of striae patellares in a girl with paratyphoid B fever.

### 565 The Myelitis of Herpes Zoster

M NICOLAS (*Thes de Paris* 1927 No 460) who records an illustrative case maintains that idiopathic herpes zoster is often accompanied by lesions of the spinal cord which on microscopical examination present the threefold lesions of inflammation, exudation and necrosis similar to those found in the spinal ganglion. These lesions involve not only the posterior cornua corresponding to the zones of the skin eruption but also the anterior cornua and the white matter. Up to a certain point these lesions may throw light on certain abnormal forms of sensory motor trophic and even cutaneous disorder. Some of the paralytic in particular can be better explained by spinal change of this kind than by a hypothetical root lesion.

### 566 Cheese Poisoning

P C CLEYNDERT jun (*Ned R. Tijdschr v Geneesl* September 24th 1927 p 1309) who records four personal cases, remarks that only a few examples of cheese poisoning have been published in Dutch literature in spite of the large amount of cheese manufactured in Holland. In the foreign literature at his disposal he could find nothing beyond a mention of cases of poisoning due to consumption of a British cheese. Van der Meer has described cases with symptoms of acute gastro-enteritis which he attributed to the large quantities of tin found in the ash of the cheese. The presence of the metal appears to be due to the use of tin instruments in the preparation of the cheese. Hillema, who has also described cases of cheese poisoning, comes to the conclusion that the symptoms are entirely due to the use of milk derived from cows suffering from foot and mouth disease. Cleyndert's patients were a man aged 40 his wife aged 34 their daughter aged 15 and their son aged 14 who about two hours after eating a Dutch cheese suffered from repeated vomiting, diarrhoea and collapse which was followed by recovery on the following day. Laboratory examination showed that the cheese produced symptoms of poisoning in mice thus indicating an abnormality in the ripening process. On further inquiry it was found that the cheese in question was about eight months old and had been prepared under cleanly conditions in a farm where no foot and mouth disease was present. The etiology of cheese poisoning is therefore still obscure.

## Surgery

### Hodgkin's Disease in Childhood

567 P BOONSANTI (*Arch Ital di Chir* September 1927 p 273), who records four illustrative cases in children aged from 3 to 4 years states that Hodgkin's disease or aleukemic lymphadenitis is not uncommon in childhood and that the small number of recorded cases is due to its being mistaken for inborn lymphadenitis owing to its situation. Histological examination of the affected tissue does not justify the term of lympho-granuloma malignum, proposed by Benda since it has no features that can be identified with any of the known granulomata. Boonsanti's hypothesis that the condition should be regarded as a special form of new growth distinct from those hitherto described is more in accordance with the clinical picture. The reproduction of the lesions in viscera provided with lymphatic tissue can thus be regarded as a true metastasis as is exemplified by the progressive spread of the disease to the internal glands liver,

spleen, intestine, and other organs. The etiology and pathogenesis are still obscure, and experimental observations do not confirm Steinberg's observations as regards the presence of tubercle bacilli or Much's discovery of granulules. The prognosis is decidedly unfavorable, and is in accordance with the hypothesis of a malignant growth. Surgical treatment, though not really efficacious, is not prejudicial, inasmuch as life may be prolonged by removal of toxic foci. Surgical treatment should be accompanied by radiotherapy, which may yield brilliant local results, although it does not justify the hope of a complete recovery. The rapid effect of irradiation of the glands is a good argument in favor of the hypothesis of a new growth, inasmuch as no inflammatory process would be so speedily affected. Although there is no recurrence of glandular enlargement, the disease assumes the form of a progressive cachexia which is invariably fatal.

#### 568 Splenectomy for Chronic Purpura

R LERICHE (*Bull et Mem Soc Nat de Chir*, November 5th, 1927, p 1132) describes the case of a boy, aged 5, who was suffering from severe epistaxis at frequent intervals. The haemorrhage had started when the child was 2½ years old, with a purpuric rash. When admitted to hospital the red cells numbered 1,400,000 per cubic millimeter, white cells 21,000, and platelets 10,000. The coagulation time was twenty minutes. The child appeared to be very thin and pale. Treatment by irradiation of the spleen and transfusions of blood from the father was started and the haemorrhage ceased. Five days later the bleeding recommenced and could not be controlled, so it was decided to remove the spleen at once. This was successfully accomplished and the bleeding stopped. Within a week the platelets numbered 110,000 and the haemorrhage had ceased. The patient, however, became steadily worse and died from intestinal obstruction, which an enterostomy failed to relieve. Leriche adds that this case shows how splenectomy in this condition definitely arrests the bleeding, and that the number of platelets are rapidly increased within a few days. He thinks that if the operation had been performed earlier it would have probably resulted in a cure of the purpura, and that it should be tried in cases of this troublesome and resistant disease.

#### 569 Sympathectomy for Angina Pectoris

M G SHELIG (*Amer Journ of Surg*, October, 1927, p 315) discusses the operative treatment of angina pectoris, and records a case of vocal cord paralysis following sympathectomy. He thinks that such a postoperative complication may check unwarranted surgical enthusiasm and furnish a corrective for assumptions about the simplicity and innocuousness of this operation. A woman, aged 58, suffering from angina pectoris, with chronic myocarditis, auricular fibrillation, and mitral insufficiency, was subjected to two operations which were followed by two types of complications, one relatively unimportant in that the patient did not resent the resultant radiating occipital and shoulder pains in view of the disappearance of the angina, and the other, a grave sequel, since dyspnoea supervened and threatened death, owing to the paralysis of both vocal cords. The literature shows considerable diversity of opinion as to the most suitable type of operation for the relief of the pains of angina pectoris, no less than ten procedures having been devised. In estimating the worth of these it has to be determined whether they do good or harm, or possibly both, to a measurable degree, combined with the fact that many patients not subjected to operation obtain spontaneous and permanent relief from pain owing to weakened heart muscle and lessened pressure. Isikowitz is quoted as affording one of the best clinical studies on which rational indications for operative therapy can be based, his attitude is one of marked conservatism, for he regards operation as a last resort, and only to be undertaken after an exhaustive clinical study of the patient and after careful and persistently applied medicinal treatment and psychotherapy. Such an investigation can only be made by an experienced physician, and Seelig adds that no other surgical procedure calls for closer co-operation between the physician and surgeon.

#### 570 Metastases in Bones following Breast Cancer

D H PATFY (*Brit Journ of Surg*, October, 1927, p 182) recalls that bony deposits secondary to carcinoma of the breast are regarded as an indication that the disease is beyond surgical aid. An account of 18 cases is given, and these are divided into three groups. In the diffuse group the bony deposits are widespread. The pelvic bones appear particularly liable to involvement, likewise the spine and ribs, while the femur was affected in several instances. The peripheral bones of the limbs are rarely involved. The prognosis in these cases is hopeless, and the only treatment is to give sedatives to relieve the pain. In the localized group deposits are found in the sternum or ribs, these cases are

open to attack by radium, and the growth can be made to disappear. The third group consists of mixed cases, where both types are seen. It is probable that the pathology of these cases is distinct. The localized recurrence may arise from the internal mammary chain or glands which have been invaded from the supraclavicular glands. The diffuse type probably results from some diffuse method of spread, either lymphatic or blood borne. The cases are too few, however, to justify conclusions on this point.

## Therapeutics.

#### 571 Whole Blood Transfusion in Pemphigus

L HOLLANDER (*Brit Journ Derm and Syph*, November, 1927, p 450) in a preliminary report records notes of six cases of pemphigus vulgaris treated by matched whole blood transfusion, since the condition was regarded as a chronic toxæmia. The diagnosis having been established, the patient's blood was typed into one of the four groups and one or more corresponding donors were selected, direct blood transfusion of from 500 to 600 c.c. was performed at weekly intervals for from three to six times. Preparation of the patient included a saline laxative the previous night and fasting for twelve hours. As a rule any reactions were negligible, though occasionally a temporary rise in temperature and pulse rate occurred, if alarming symptoms appeared the administration of one tenth of a grain of morphine sulphate, repeated two or three times, exercised a quieting influence. Should tingling or numbness of the extremities, palpitation, air hunger, or cyanosis occur the injection of 10 minims of a heparine chloride, 1 in 1,000, intradermally is advocated. In five of the six cases marked improvement in both the general and skin condition resulted, and in the sixth case the skin condition became markedly better, but death occurred from an intercurrent acute infection. Hollander considers that these results render a wider investigation desirable, even if it should be shown that improvement may only be temporary. He suggests that other serious dermatological conditions, such as exfoliative dermatitis, may derive benefit from blood transfusion.

#### 572 Treatment of Amoebic Infestation

O WILLNER (*Medicine*, September, 1927, p 341) reviews the drugs introduced in recent years for the treatment of amoebiasis. He remarks that the percentages of permanent cures in cases treated with emetine are not high (28 to 70 per cent), and that there has been a constant tendency to give larger doses of the drug, with the result that toxic doses are almost always administered. The period of invalidism after a course of emetine, especially in cases having little impairment of general health and ability to work, appears neither tolerable nor economic. Various adjuvant factors have been used with emetine: bismuth subnitrate with or without Fowler's salts, native plants of local reputation, 40 per cent sugar solutions as enemata, and diets of protein or milk have been tried with sometimes apparently good clinical results. Yatien, a proprietary preparation, was tried first in amoebiasis as a 5 per cent enemata solution, later the strength has been reduced to 1 to 1.5 per cent. It is also given in wafers, gelatin capsules, and pills by the mouth, the total daily dosage being up to 3 grams. Courses of yatien, combining its introduction by the mouth and enema, are given over three weeks, the patient being preferably in hospital for the first week. The results in old chronic cases uncurd by all previous treatment are described as spectacular. Amoebae usually disappeared from the stools by the third day, and in 79 out of 88 cases treated at the Peking Union Medical College Hospital the stools were free after three to six months. Two other drugs, both arsenicals, stovarsol and treparsol, have recently been introduced. The results with stovarsol are said to compare favourably with those of other drugs, but there is an element of uncertainty in its action and perhaps sometimes of danger, of the correct dose is not yet sufficiently established. Treparsol contains more arsenic, but it is more slowly eliminated and is less toxic than stovarsol, it has been found useful with or after a course of emetine, and can be given subcutaneously or, better, intramuscularly. Willner cites the results of the Willmore and Vaindiale with an arsine dye, auramine, the hydrochloride of tetramethyl diamino diphenyl isocyanine, a combination of this with emetine is known as arsenic dye. The advantages claimed for this drug are freedom from the toxic effects, that it is less depressing than emetine, and that treatment in bed is unnecessary. Large doses of bismuth subnitrate are a valuable adjuvant. Courses of treatment are given for acute, chronic or carrier, and hepatic cases. Of 40 cases treated, among them many severe and stubborn—the residue of prisoners infected during the war—7 regained their health and lost all signs of the disease, and the

stools remained free from cysts for at least six months. The drug was used in association with stovarsol and bismuth except where the liver was involved, when emetion hydrochloride was given. The author concludes that yafren is the most generally useful drug, it is the least toxic and most widely applicable of the remedies.

### 573. Hexyl Resorcinol in Infections of the Urinary Tract.

C. W. EBERBACH and R. D. ARN (Journ. Amer. Med. Assoc., August 13, 1927, p. 512) refer to the literature describing the use of hexyl resorcinol in urinary infections (see *Epitome*, 1925, vol. 1, paras. 1-6 and 2-0; vol. 11, para. 245; 1926, vol. 1, paras. 101 and 625). They report the results of using the drug in some 200 cases with rather less benefit than that usually recorded, but they attribute this relative failure to the fact that the pathological conditions were mainly chronic rather than acute. They conclude that hexyl resorcinol will cure about one third of all types of urinary tract infection, when the primary foci have been removed. They found that there was rapid and continued relief of the symptoms, and they add that the earlier in the course of the disease this treatment is begun the greater is the chance of a cure. In mixed infections so treated the cocci often disappear from the urine while colon bacilli remain. They believe that the use of this remedy in conjunction with other therapeutic methods will result in a considerably higher proportion of cures being obtained.

## Neurology and Psychology.

### 574. Home Treatment of Mental Patients.

ACCORDING TO J. RAECKE (*Med. Welt*, October 15th, 1927, p. 1392) the modern tendency in Germany and elsewhere is to limit asylum treatment largely to those mental patients who have acute and violent symptoms and are a danger to themselves or their surroundings. Convalescent patients, also, are discharged from institutions earlier than was formerly customary. The author considers that this benefits the patient by preventing him from becoming unnecessarily alienated from his normal surroundings. In manic depressive states institutional treatment is generally desirable in all but the mildest cases, in which rest, warm packs, and sedatives may be tried. Epileptic psychoses are also not safely treated at home as a rule, but for cases of schizophrenia which are frequently psychically progressive with remissions, Raecke considers that institutional treatment is often definitely detrimental and that exacerbations are frequently due to factors in the environment. He therefore advocates that early cases should be treated at home, and considers that at this stage much can be done by gaining the patient's confidence, suitably organizing his occupations in accordance with a definite daily routine and prescribing stimulating or sedative measures according to the nature of the case, besides eliminating so far as possible irritant factors from the environment and explaining the need for leniency to the patient's friends. On theoretical grounds, glandular therapy may be tried. In paranoia much may also be achieved by patient attention to such matters as delusions of persecution, which will sometimes reveal that they have some small foundation in fact. For the *malaria therapy* of incipient general paralysis institutional treatment is necessary, but during remissions the patients should be carefully watched for recurrence of symptoms, and excessive mental or physical effort be avoided. Cases of senile dementia and arterio-sclerotic psychoses are comparatively easily treated at home though careful supervision of the patient is necessary. In the latter type narcotic drugs are of less value than cardiac. Neuroses do not generally require institutional treatment; it is important in these also to discover and if possible remove external factors producing the particular type of mental reaction and to induce the patient to lead an equable life with adequate rest and avoidance of hurry. For alcoholism and other intoxication psychoses treatment in a suitable home is essential.

### 575. Katatony and Extrapyramidal Syndromes.

P. GUIRAUD (*Paris m. d.*, October 15th, 1927, p. 301) maintains that in the study of katatony it is wise to note the slight symptoms and that the collecting of these, which are of very different value and etiology into such groups as mannerism, negativism, suggestibility and stereotypia only leads to diagnostic errors. He classifies the symptoms as vegetative, extrapyramidal and psychomotor. In the vegetative group are included ocular troubles, muscular and vasomotor disturbances, secretory and trophic derangements, disturbances of the vital activities, troubles probably of tuber cinereal origin, hypo-excitability to pharmacodynamic agents, and

hyalanthine in (or hypo) excitability. This syndrome is due to lesions of the vegetative reflex centres which lie in the pons as far as the infundibular and hypothalamic regions, and are connected with sympathetic ganglia. In early katatonic dementia it is often very accentuated and it is present in many other extrapyramidal syndromes, particularly in post-encephalitic Parkinsonism. In the extrapyramidal group the most important symptom is the conservation of imposed attitudes and Guiraud asserts that this is of extrapyramidal origin and not psychogenic or voluntary. Other symptoms in this group are motor repetitions or frequentative movements, the elastic stereotypia, tonic anomalies of the agonists and antagonists in voluntary movements, abnormal movements, as myoclonus and grimaces and certain motor episodes as apoplectic or epileptic seizures. Further proofs of the extrapyramidal origin of katatony are the tremors present in both early dementia and Parkinsonism, typical katatonic symptoms are not rare in epidemic encephalitis, the immunity of vegetative symptoms manifestly mesocephalic shows a well-known localization of the katatonic and Parkinsonian syndromes, between the locus niger and the anterior extremity of the caudate nucleus, i.e. a mass of grey centres and white bodies which are the seat of very different syndromes and the caudate nucleus appears to play an important part in the abnormal movements and in some exceptional cases the motor symptoms are noticed before any mental trouble and first attract the patient's attention. Psychomotor symptoms are manifested by a defect in starting ordered or desired acts by the ceasing or interrupting of ordered acts by motor diminution, and by ideatory or ideomotor dyspraxias through failure of attention or interest. The author believes that the origin of these symptoms is subcortical and lies in the thalamus rather than in the cortex. In conclusion he states that there is no reason to believe that all psychic disturbance is cortical in many mental conditions the grey nuclei play an important part and influence both the psychic state and its motor expression.

### 576. Pseudo tabetic Ataxia.

G. MARINESCO (*Rev. Neurolog.*, October 1927, p. 337) states that ataxia troubles have long been noted in the course of many infectious diseases and Dejerine has shown that this polyneuritic pseudo ataxia (which he terms *nervo tabes*) is distinguished from true locomotor ataxia in due to an alteration of the roots and columns but to lesions of the peripheral nerves. *Nervo tabes* is characterized by lightning or lacerating pains, acute thesis, anaesthesia, a very pronounced alteration of the deep sensibilities, a peculiarity of the sense of attitudes and inco-ordination in the limbs which is exaggerated by closing the eyes, a certain degree of motor paresis and muscular atrophy, the presence of Ponberg's sign and the abolition of tendon reflexes. It is differentiated from true tabes by its rapid evolution in some weeks or months, absence of the Argyll Robertson pupil and of sphincter troubles, pain on pressure over the nerve trunks and muscles and by its topography. Dejerine in necropsies on two cases found that the marrow, the anterior roots and the spinal ganglia were absolutely healthy, while the nerves of the limbs especially at their distal extremities showed degenerative changes. Marinesco reports a case in a woman aged 73 which proves by its duration, its evolution and the lesions in the nervous system that the problem of *nervo tabes* is really more complex. In this patient the disease had started only one month previously the classical symptoms were noted, the Wassermann reaction was negative but the tabes had been preceded by an attack of pneumonia. At the necropsy the peripheral nerves of the lower limbs showed a degeneration of the fibres and a perivascular and interstitial inflammation. Manifest changes were seen in the nerves of the skin and in the corpuscles of Pacini and Meissner. In the globus pallidus was found a heavy disintegration of iron and the cytoplasm of many of the cells of the microglia contained ferrogranules. No lesions were noted in the cerebellum. The meninges of the cerebral cortex showed a fibrosis of the cells more marked around thickened capillaries, and associated with small areas of softening. In addition particularly in the occipital and frontal lobes were seen numerous so-called senile plaques. Marinesco believes that these commence by the deposit of an acicular substance and as they develop they cause a reaction in the microglia and adjoining neuroglia, their origin is probably in the blood plasma as they are found in great quantities in the perivascular spaces. At first these deposits cause no degeneration of the neuroglia or nerves, but as they enlarge they exercise a destructive action either by their size or their pathogenic properties. When the microglia hypertrophies it sends out fine prolongations which penetrate to the interior of the plaque and form a mesh of rods or filaments on its surface. The nuclei of certain plaques seem to act as necrotic elements. These plaques are not phenomena of normal senescence. While

many pneumococci were found in sections of the lungs none were discovered in those of the neuraxis, and Marinisco believes that the lesions in the latter were caused by a filterable virus which had invaded this system through the pulmonary passages

### Etiology of Puerperal Fever

P. VELASCO (*Arch de med, cu y esp*, October 29th, 1927, p 493), after alluding to the prevalence of puerperal fever in Spain, maintains that cases of puerperal infection can be divided into two clinical types according as the prognosis is favourable or the reverse. The diagnosis of an infection which was formerly based on the clinical symptoms can now be made by bacteriological examination of the blood. Three positive blood cultures suggest that the focus of infection is within the body, and if it cannot be found the possibility of endocarditis should always be considered. In cases of puerperal patients with high fever and repeatedly negative blood cultures the cause of the fever should be sought for in other infections such as tuberculosis, influenza, or typhoid fever. An important factor in the prognosis is the localization of the infecting organism. Infection of the endometrium is of much less gravity than parametritis, the latter is less serious than thrombophlebitis, which in its turn is less deadly than endocarditis. The nature of the organism has also a certain prognostic value, the presence of *B. coli*, for instance, in spite of the high fever accompanying it, allowing a much better prognosis than in the case of the haemolytic streptococcus. Velasco adds that in the treatment of puerperal infection based on etiological principles blood cultures are extremely useful, not only permitting the practitioner to adopt a successful method such as using an antistaphylococcal serum in cases of infection by Fraenkel's *Bacillus pyrogenus*, but also enabling him to test the efficacy of his treatment.

### A Method of Preventing Perineal Tears

L. DROSIN (*Med Journ and Record*, September 21st, 1927, p 363) has found a method which he calls "bloodless episiotomy" useful in stretching the perineum immediately before delivery in a large number of cases, particularly in primiparae. When the perineum is bulging and the caput haemorrhoidale visible the distal two thirds of the index and middle fingers of one or both hands are inserted flexed into the vagina with their palmar surfaces in contact with the posterior vaginal wall and eight or ten rapid vibratory movements in an antero-posterior direction are carried out without the use of force, keeping the fingers all the time in contact with the mucous membrane, so that the force actually employed is only gauged by the resilience of the underlying tissues, the second part of the manoeuvre is to stretch the levatores and fourchette by similar vibratory movements up and down with the same fingers nearly extended, while in the third part the fingers are held flexed on either side inside the vaginal orifice with the tips in front of the levatores and the movements are repeated in a downward and outward direction. If the perineum is very rigid the set of movements may be repeated at intervals of three or four minutes. Drosin finds that tears are reduced to a minimum by this method, and that those which do occur are sutured more easily than those produced by deliberately incising the perineum as in lateral episiotomy.

579

### Pituitrin in Labour

J. W. T. WILLINK (*Nederl Tijdschr v Geneesk*, September 3rd, 1927, p 966) during the period 1921-26 used intramuscular injections of pituitrin in 203 out of 500 deliveries, 92 of the patients being primiparae and 111 multiparae. The injection was repeated when necessary. It very rarely had occasion to give more than 0.5 c.c. The results were as follows. In 75 per cent there was a satisfactory strengthening of the pains. Post-partum haemorrhage occurred in only 9 cases, and forceps deliveries in 10 cases with no deaths. The duration of labour in primiparae was, on the average, eighteen hours, and only one child died during birth. The total infant mortality (not including macerated foetuses) was 4, and asphyxia occurred in only one case.

### 580 Treatment of Chronic Gonorrhoea in Women

A. LOESER (*Amst Journ Obstet and Gynecol*, September, 1927, p 329) reports a series of 118 women, suffering from chronic gonorrhoea, treated by subcutaneous injections of a suspension of living gonococci. A twenty-four to forty-eight hours' culture on isotonic blood agar was washed off with sterile saline solution, and a dose of between one and eight thousand million was injected subcutaneously into the

upper arm. Within twenty-four hours the growth can be made to infiltrate. There was also slight local growth can be made to usually headache, but this and the local recurrence may arise never attended with evil after effects. Glands which have been enter the blood stream, and that the method of spread, either were cured with one injection, repeated method of spread, either swabs being negative. Only true chronic are too low, however, for this form of treatment, the patient, struating, and must not have had any local ment during the previous two months.

## Pathology.

### Infection with Single Tubercle Bacilli

L. WAMOSCHER and H. STOECKLIN (*Centralbl f Bakt*, 1927, vol 104, Beiheft, p 86) describe how, with the aid of Peteril's micromanipulator, they have been able to perform infection experiments on animals, using single bacilli. Wamoscher and his colleagues had shown that it was possible to produce a fatal disease in white mice by the subcutaneous injection of a single pneumococcus, streptococcus, or anthrax bacillus, the proportion of successful results obtained with these three organisms was 24, 32, and 28 per cent respectively. In the present paper they describe experiments on guinea pigs with the tubercle bacillus, introduced into a subcutaneous pocket in the thigh. In one series of experiments they used a four weeks old culture of the human type in glycerine broth. Thirty-eight animals were each infected with one bacillus, eight animals with two bacilli, and one animal with thirty to forty. The animals were kept on a low diet for eight weeks after injection, with the idea of diminishing their resistance, after that time they were fed freely. Romer tests were performed before injection and eight weeks after. Guinea pigs which gave a positive Romer test eight weeks after injection and had palpable inguinal glands were considered to be suffering from tuberculosis. The results of this experiment were unsatisfactory, none of the animals injected with one bacillus developed tuberculosis, and of the eight animals injected with two bacilli only one was infected, but the guinea pig which received thirty to forty organisms became tuberculous. In another experiment they used a nineteen to twenty day old culture of human type on Lubanau's medium. Thirty-eight animals received one bacillus, of these 40 per cent were infected. Nine animals were injected with two bacilli, of these 67 per cent became tuberculous. The poor results of the first experiment are attributed to the use of an old culture containing too many dead organisms, and the authors conclude that it is possible to infect guinea pigs with a single tubercle bacillus.

### 582 The Action of Sodium Salicylate in Large Doses

D. LIOTTA (*Riv Med*, October 17th, 1927, p 985) publishes the results of a series of experiments performed by him, with a view to ascertain the effects of prolonged administration of full doses of sodium salicylate alone, and in combination with sodium bicarbonate. To one set of rabbits he gave full doses of salicylate alone and to another group a mixture of this salt and sodium bicarbonate. His experiments showed clearly that the salicylate alone might cause serious changes in the kidney, liver, and heart, and to a less degree in the pancreas and suprarenals. The most marked changes were seen in the kidney, and the author gives microphotographs of the appearances. In the animals treated with a mixture of sodium salicylate and bicarbonate none of these changes were noted.

### 583 Estimation of the Diphtheria antitoxin Content of Human Serum

G. RAMON and C. ZOELLER (*C R Soc de Biologie*, October 28th, 1927, p 1153) have applied the flocculation method to estimating the antitoxin content of human serum. Serum was taken from twelve Schick negative persons, who had become immunized to diphtheria by an attack of the disease, by latent infections, or by injections of antitoxin. This serum was tested by Ehrlich's method on guinea pigs, and by the *in vitro* flocculation technique. It was found that the two methods gave closely similar results. The authors conclude that the flocculation method can advantageously be applied to man. Since, however, the precipitate resulting from the mixture of toxin and antitoxin is visible only when these substances are present in sufficient quantities they consider that the flocculation method will not be applicable to human serum unless this contains one or more units of antitoxin, if a lower concentration of antitoxin is present the method will be unsuitable.

stool's remained free from a drug, was used in a case of escape where the liver was chloroform given. The most generally useful and widely applicable of the

### 573. Hexyl Resorcin

### Medicine.

C. W. LEBFACH on *an diphtherial Croup*

August 13th, 1927, p. 1075 (*Le St. 1* September 17th, 1927). A group of cases of acute laryngitis of a non-use of hexyl resorcin in which the clinical picture is identical with the diphtherial croup due to diphtheria bacilli. These cases are extremely embarrassing and from the clinical, prognostic and therapeutic aspects. Moreover, they are relatively frequent, during the last two years 1 out of 10 has observed ten typical cases and he has gained the impression that non diphtherial croup is as frequent as true diphtherial laryngitis. This apparently paradoxical conclusion is explained by the fact that the incidence of diphtheria in Brussels at the present time is low, and that the disease assumes a mild form. These cases of non diphtherial croup may be classified as due to influenza, measles, scarlet fever, infection tuberculosis, syphilis, the *O. tum. albus* and general infections such as typhoid fever, small pox, varicella, erysipelas, and burns. Non diphtherial membranous laryngitis is due to staphylococci, streptococci or diplococci and its diagnosis is impossible without bacteriological examination. The prognosis is not the same in all cases, of non diphtherial croup but depends on the causal agent. In influenza croup which is the most frequent form the mortality of 25 per cent given by Requin corresponds with Fonteyne's observations. Generally speaking the prognosis is aggravated by the following factors: (1) Ulceration or even laceration of the laryngeal mucous membrane owing to the intensity and long duration of the spasm which they produce. (2) The occurrence of broncho pneumonia which indicates a virulent and extensive infection. (3) Necessity of intubation or tracheotomy which favours the onset of the complications mentioned in (1) and (2). As regards treatment while it is the rule to give serum in doubtful cases needless injections should be avoided to prevent the patient being rendered hypersensitive to subsequent injections. The most important indication is to combat the spasm by drugs such as cocaine, morphine, and chloral so as to save the patient from intubation or tracheotomy, which renders the prognosis considerably more gloomy.

### 585

### Writer's Cramp

WHILE granting that muscular overwork and psychic conditions are factors in the etiology of writer's cramp, ANDRE THOMAS and SALVET (Paris med., October 1st 1927, p. 243) assert that the mode of action of these factors has not been elucidated. The number of dystonic syndromes following even slight wounds shows the effect of localized peripheral irritants on muscular motility. The presence of dystonia comparable with writer's cramp in encephalitis and the appearance in this disease of cramp or dystonia on writing have suggested comparison between the lesions observed after death in encephalitic subjects and the physiological pathology of cramp. Lemos believes that the lesions may be either central or peripheral, and that cramp of central origin depends on a lesion of the corpus striatum. The co-occurrence of spasmodic torticollis and writer's cramp has been noted by Duchenne and Souques believes that these diseases, together with certain other spasms, are related to disturbances of the corpus striatum. Lemos has reported a case of a labourer showing the Pulvinar syndrome of encephalitis in which there was progressive rigidity of the arm during writing, and falling of food. The authors state that the cramp seemed to result from a hyper- and a struggle between the antagonistic muscles which enter into the mechanism of writing. They describe in detail four cases of classical writer's cramp which were completely free from all Parkinsonian rigidity and other organic affections of the nervous system. In these the neurological examinations were constantly negative and a hyper-thetia of the antagonistic muscles was found to exist during the tests of passivity and balancing of the limbs segment by segment. This resistance to passive movements is manifested whether the reaction is caused by agitation of the limb or by electric contraction of the antagonistic muscles and the hyperactivity of these is lasting and can be found several months after ceasing to write. The interpretation of this symptom is difficult and the authors advance various hypotheses. It is possible that different sets, by their repetition (simulating overwork) may disturb the functioning of the motor co-ordinating and regulating centres. The fact that cramp does not affect all writers seems to point to pre-

disposition and the ease with which, in some patients, the cramp passes to the left hand when it is used to assist the right supports this view. The unilaterality of the symptom, always localized in the right hand, is against the theory that it is primary and antecedent to the cramp. The authors believe that it is acquired. They also maintain that the psycho-emotive factor plays a great part in causing the cramp, that the cramp is of a complex mechanism in which are associated different elements of the psycho-emotive and motor spheres and that it is dominated by the personal character of the patient.

### 586

### 'Prophylaxis of Varicella

W. W. WADDELL, Jun., and R. ELLI (Brit. Jour. Dis. Child., October, 1927, p. 540) allude to the series of cases reported by Greenhalgh (*Epitome* October 2nd 1925, para. 283), and report 23 cases in which persons exposed to varicella were inoculated against the disease. After a negative Wassermann reaction had been obtained in the donor the contents of a vesicle which had first been cleaved with boric acid and then with saline solution were removed by a small capillary tube and the vaccination was then performed according to the method of vaccinating against small pox. Six gave histories of previous attacks of varicella and in one the history was uncertain. Of the 23 persons vaccinated 8 showed a successful reaction as evidenced by the formation of a papule-vesicle and crust at the site of inoculation. Five cases of trunk varicella subsequently developed. 3 more patients showed so slight an eruption that it was classified as vaccinia and 3 patients appeared to have been rendered immune. As there was difficulty in obtaining positive reactions in a large percentage of cases and several patients developed varicella in spite of successful vaccination it is doubtful if the method can be successfully employed as a means of preventing varicella in hospitals and institutions for children.

### 587

### Influenza and Tuberculosis

R. GAETA (Il Politecnico Sez. Prat., September 12th, 1927, p. 1318) states that many children under his observation who had escaped influenza last year developed an attack towards the end of May and in June of the present year. There was always lobar pneumonia with special predilection for the apices, either the right or left or both consecutively. Examination of the sputum showed the presence of Pfeiffer's bacillus associated with streptococci and other organisms. Gaeta remarks that the influenza bacillus thus shows the same tendency to attack the pulmonary apices as the tubercle bacillus. Influenza, therefore, like measles and whooping cough may be regarded as a pre-eminent tuberculo-genic disease.

## Surgery

### 588 Diagnostic Errors in Extreme Gastric Dilatation

W. MILLS (*Centralblatt f. Chir.* November 12th, 1927, p. 2895) describes two cases of extreme gastric dilatation in which errors of diagnosis were made. A man, aged 47, was admitted to hospital with symptoms of acute gastric perforation. For many years he had suffered from hyperacidity and severe pain. The abdomen was opened under ether anaesthesia and the stomach was found to be enormously dilated. It contained five litres of thick greenish slimy fluid which was removed. Subsequent exploration revealed pyloric stenosis due to scarring. Gastro-enterostomy relieved all symptoms and the patient made an uninterrupted recovery. The second patient was a girl, aged 17, who had drunk a solution of caustic soda four weeks previously. For the first eight days subsequently she was unable to swallow after which she could swallow fluids with much pain and difficulty. She was emaciated and had a 'scaphoid' abdomen but no abnormality could be found. The oesophagus could be dilated temporarily with filiform bougies but was otherwise impermeable. Any attempt at swallowing caused severe retching and hiccup, followed by vomiting of a little mucus. Ten days later the patient complained of gripping abdominal pain. Examination showed in the left hypochondrium a definitely fluctuating dull tender swelling as large as a child's head. It did not move with respiration but was slightly mobile laterally. After inflating the rectum there was a tympanic note over the tumour, and a silencing

**MEDICAL LITERATURE**

which no treatment is given. He is convinced that what ever the underlying cause of this condition may be, prolonged tobacco smoking is the immediate etiological factor, though the vast majority of smokers never develop signs of the disease. He concludes that some additional factor is present, possibly a predisposition to vascular disease, or special susceptibility to the effects of tobacco poison, in patients in whom thrombo angitis obliterans develops. Cessation of smoking is the most important therapeutic measure.

**Arsenobenzol and Quinine in the Treatment of Trigeminal Neuralgia**  
Soc. Prat., October 17th, p. 14

593 **Ethylhydrocupreine in Lobar Pneumonia.** F. B. CROSS (*Med Town and Record*, September 7th, 1927, p 271, and September 21st, p 354) advocates the employment of nunoquin base (ethylhydrocupreine) in the treatment of lobar pneumonia, in view of its action on pneumococci and the clinical improvement following its employment. It is administered with 5 or 6 oz. of milk. It has been found to reduce the temperature, render the patient more comfortable, and decrease the tendency to extension of the lesion. It is probably advisable to use this treatment only in the first three days of lobar pneumonia, the dose suggested is 4 grains every four or five hours up to a total of fifteen doses. In a series of 3,008 cases the death rate was only 5.08 per cent. Cross also finds the remedy valuable as a prophylactic in respiratory influenza, chest traumatism, with or without fracture of the ribs, and in congestion of the lungs, after anaesthesia. Before this quino derivative was employed as an insoluble base, optic neuritis, amblyopia, and permanent blindness were reported in some cases, but the author in his own series has observed no untoward effects other than tinnitus aurium in six cases, nausea and vomiting in four, and profuse diaphoresis and headache, each in one case. He advises the discontinuance of the treatment when ever it becomes clear that it is disagreeing with the patient.

594 **Hexyl Resorcinol as a Tissue Disinfectant.**  
V LEONARD, and W A PEIRER (Surg, Gynecol and Obstet, November, 1927, p 603) consider that hexyl resorcinol, in addition to being a primary antiseptic, can be used with advantage in other conditions where a non-toxic bactericidal agent is required. The solution recommended contains 30 per cent of glycerin and 70 per cent of water, in each cubic centimetre is dissolved 1 mg of crystalline hexylresorcinol. This solution was found to be stable and to destroy most pathogenic micro organisms in less than fifteen seconds. The surface tension is very low, and the hexyl resorcinol remains in perfect solution in all dilutions. It has no smell and is colourless, it is not affected by any of the heavy metals. The authors advocate its employment for irrigation of any tissue surface when a considerable bulk of fluid is required, and also for wet dressings on infected wounds, and denuded surfaces. They add that when diluted with 1:10

590 **Sacro iliac Subluxation and Backache**  
H. H. COX (*Surg., Gynecol. and Obstet.*, November, 1927, p. 637) in considering sacro iliac subluxations as a cause of backache classifies them as mainly acute or traumatic and chronic or postural. He adds that relaxation of the joints occurs during pregnancy, parturition, and menstruation, and as a consequence of arthritic disease. In acute cases the onset is sudden, while in chronic cases it is gradual, insidious and shows marked prominence of the sacrum, spasm of rigidity of the spinal muscles, obliteration of the lumbar curvature, and tenderness over the joint. By fluid Treatment aims at restoring the normal relations between the sacrum and ilium and the application of a suitable support. Cox describes the following therapeutic manipulations. The patient lies face downwards on the table and grasps its edge while supporting his weight by the elbows and abdomen. The surgeon, standing on the table so that it is supported above by the body, clear of the table so that it is supported above by the elbows alone. With the legs in abduction and steady traction on the affected leg the body is lifted up and down for several minutes whilst an assistant firmly presses over the sacrum. As the bones slip into place sudden relief is obtained with restoration of the lumbar curve. By this method the joint is placed in the position of hyperextension which it occupied at the time of displacement. A firm support of strapping is passed behind from below the level of one great trochanter to the other and well down on the buttocks and the patient is kept in bed for a week. Cox states that in the great majority of acute cases this treatment is fully effective, but the patient should be cautioned against slipping, stooping with the knees stiff, and sudden twisting or running, since recurrences are frequent within the first six months.

591 **Treatment of Thrombo-angitis Obliterans**  
S SILBERT (*Journal Amer Med Assoc*, September 17th, 1927, p 964) reports a series of 258 patients with thrombo-angitis obliterans in whom the symptoms began before the age of 45. In 137 patients amputation of one or both lower extremities was performed, and in 120 of these the operation fell within five years of the onset of symptoms. In 121 patients no amputation was performed, and the spontaneous course exceeded five years in only 18 cases. It is concluded, therefore, that 77 per cent of such patients will require amputation within five years from the onset of symptoms, unless treatment is provided. In comparison with these results Silbert reports that 84 patients were treated with intravenous injections of hypertonic salt solution, and so far only 10 patients (12 per cent) have required amputation in 5 of these cases gangrene of the toes was already present when treatment started, so the true percentage is lower still. He thinks that this result suggests the possibility that such therapeutic treatment may be beneficial, but he insists that in assessing the benefit of this and other procedures it is important to compare the results statistically with those in

594 **Hexyl Resorcinol as a Tissue Disinfectant.**  
V LEONARD, and W A PEIRER (Surg, Gynecol and Obstet, November, 1927, p 603) consider that hexyl resorcinol, in addition to being a primary antiseptic, can be used with advantage in other conditions where a non-toxic bactericidal agent is required. The solution recommended contains 30 per cent of glycerin and 70 per cent of water, in each cubic centimetre is dissolved 1 mg of crystalline hexylresorcinol. This solution was found to be stable and to destroy most pathogenic micro organisms in less than fifteen seconds. The surface tension is very low, and the hexyl resorcinol remains in perfect solution in all dilutions. It has no smell and is colourless, it is not affected by any of the heavy metals. The authors advocate its employment for irrigation of any tissue surface when a considerable bulk of fluid is required, and also for wet dressings on infected wounds, and denuded surfaces. They add that when diluted with 1:10

volumes of water it may be instilled in the normal con-  
junctival sac. The undiluted solution may also be used for  
irrigation of the urethra, bladder and kidney, for fresh cuts and  
abrasions, for granululating surfaces and in abscess cavities,  
sinuses, and affections of the ear, nose, throat and mouth.

#### 595 Adrenaline in Infantile Eczema

J. D. PILCHER (*Journ Amer Med Assoc*, July 10th 1927, p. 110) recommends subcutaneous or intramuscular injection of adrenaline for infants from 5 to 14 months old suffering from the irritation of eczematous conditions. Relief followed within two minutes of the administration and persisted for an hour or more, the patient often falling into a restful sleep. The dose given was from 0.1 to 0.3 cc. of the 1 in 1,000 solution and no harmful results ensued. Pilcher thinks that the relatively large dose is necessary for benefit to follow.

## Laryngology and Otology.

#### 596 Papillomata of the Fauces

R. MOTTA (*Arch Ital di Otol*, August 1927 p. 493) has minutely examined a series of papillomata of the uvula, pillars of the fauces, soft palate, palatine and lingual tonsils, and the tongue. The growths were all simple papillomata with in the main typical histological characters. There was a very considerable overgrowth of the epidermis with great multiplication of the basal layer. There was not such a massive overgrowth of the underlying connective tissue but a particular arrangement of this layer and of the blood vessels was found. Long narrow columns of connective tissue with a rich vascular network passed downwards into the thick mass of epidermal cells and in some cases they branched. It appeared that these columns were endeavouring to supply all the cells of the tumour but had difficulty in maintaining an adequate supply. The cells that lay close to the vascular tissue were well formed and took the stain well, those that lay at a distance were irregular and flattened and stained very poorly. Where there was a lack of vascular connective tissue there was a considerable amount of keratinization. The tumours which were white had the least blood supply and the highest degree of hyperkeratosis, the pinker forms had a better blood supply and a lower degree of keratosis. From the study of the sections the author considers it probable that the capillaries are caused to proliferate by some unknown stimulus by their overgrowth the cells of the epidermis are stimulated to multiply to a very considerable extent. This action having been set in motion the epidermis has a great tendency to outgrow its blood supply continually and cell degeneration follows, giving rise to the familiar keratinized surfaces of papillomata of the fauces.

#### 597 Antral Suppuration treated by B. bulgaricus Applications

MESSINGER (*Bratislavské Lekárske Listy* October 1927 p. 429) describes the method of treatment of acute subacute and chronic suppuration of the antrum of *H. influenza* by means of a five days old culture of the Bulgarian bacillus in milk. The antrum was filled with the milk culture every second or third day. In the opinion of the author this method surpasses all others tried up to the present. The best results were achieved in cases where the suppuration was due to an inflammatory condition of the mucous membrane only. Where the bone was also involved the benefit was less and the condition was at the most, only improved by the treatment. The surgical opening of the antrum being the only way of obtaining definite cure.

#### 598 Treatment of Malignant Tumours of the Post-Nasal Space.

ACCORDING to A. BARANGER (*Arch Internat de Laryngol, d'Otol et de Rhinol*, July-August 1927 p. 827) treatment of malignant tumours in the post-nasal space is difficult owing to the very high degree of malignancy and to the site of the growth in a cavity surrounded by masses of bone with very important organs close by. Medical procedures include palliative injections of formalin alcohol or adrenaline and the application of methylene blue, these are designed to reduce sepsis and to cause the tumour to shrink. Injections of copper quinine, and arsenic may be used in an attempt to destroy the tumour but they are not attended with any better results here than in any other part of the body. Surgical treatment consists in removing the tumour through the mouth but it is usually followed by recurrence at an early date. The use of other routes such as the lateral nasal gives better results and a much better chance of eradicating the tumour is provided. The author does not rely on diathermy. He considers it useful for reducing the size of

the growth but it has no selective action and can only be palliative in this region, there is, however, no haemorrhage and no damage to other structures. Radium and x-rays offer the best hope of success. When the growth is limited and circumscribed it is found that the gamma rays of radium are more localized and more selective than x-rays. In cases where the tumour is not circumscribed it is found that x-rays, being less localized in action, give distinctly better results. Lympho-sarcoma which rapidly under this treatment, but reappear in other parts of the body. Lymphoma disappear more slowly, and when they recur they do so locally and with less rapidity.

#### 599

#### Otitis in Influenza.

P. VACHEZ (*These de Paris* 1927 No. 260), who reviews the literature and records seven illustrative cases in patients aged from 9 to 48 years states that influenza otitis is characterized by its sudden onset and violent pain. Two subsequent stages may be described. The first is one of hyperaemia manifested by a diminution of hearing and a sense of fullness in the ear. When the condition becomes worse the patient complains of a more or less dull continuous pain in the ear radiating to the temporal region. On examination the tympanic membrane is seen to be of a uniform dark red colour and sometimes the ossicles cannot be distinguished. Interstitial haemorrhages may develop and give rise to the appearance of haemorrhagic vesicles on the membrane and walls of the external auditory meatus. The stage of hyperaemia is usually followed unless paracentesis is performed by a stage of exudation in which there is an effusion into the middle ear cavity, pressure on the membrane and walls of the tympanum and gromm, rise to severe and continuous pain. On examination the membrane is seen to be oedematous and bulging into the meatus. Paracentesis is followed by a discharge of blood stained pus and relief of the pain. In rare cases influenza otitis is purulent from the first. In addition to the form which runs its course in two stages is one ushered in by severe constitutional disturbance and affection of hearing. On examination haemorrhagic vesicles are seen to cover a more or less considerable extent of the tympanic membrane, the rest of which remains normal. There are also numerous vesicles in the meatus the lumen of which is sometimes completely blocked. The meatus becomes tender on pressure at an early stage. The most characteristic feature however of this form of otitis is the rapid disappearance of the alarming initial signs in the absence of any treatment or after antiseptic applications to the nasal fossae, nasopharynx and external auditory meatus.

## Obstetrics and Gynaecology.

#### 600 Acute Appendicitis Complicating Pregnancy

R. A. WILSON (*Surg Gynecol and Obstet* November 1927, p. 620) reports ten cases of pregnancy complicated by appendicitis and discusses the acute condition when complicating pregnancy labour, and the puerperium from the point of view of frequency, etiology, symptomatology, diagnosis, prognosis and treatment. Primary acute attacks of appendicitis occasionally arise during pregnancy but not more frequently than in the non-pregnant woman and while the symptoms are generally typical in early pregnancy they are more likely to be misleading and obscure during the later months and to be mistaken for an early ectopic gestation, pyelitis, or the pains of commencing labour so that valuable time may be lost. If operated upon before rupture the mortality is practically nil but when once perforation has occurred it rises to from 40 to 60 per cent. As a means of prophylaxis even a normal appendix should be removed when practicable during a laparotomy performed for other conditions and when a married woman is known to have a diseased appendix it should be removed before she becomes pregnant, or if pregnant on the first appearance of symptoms. During the first seven months treatment is essentially the same as for a case in the non-pregnant but during the last two months if perforation has occurred the uterus should be emptied at the time of operation. In the presence of marked peritonitis a rapid Porro operation offers the best chance of free drainage and the complete removal of infected tissue but the choice of procedure depends upon the extent to which the uterine wall is involved in the infectious process.

#### 601

#### Peritoneal Endometriosis

J. A. SAMPSON (*Amer Journ Obstet and Gynecol* October, 1927 p. 422) asserts that peritoneal endometriosis sometimes arises from the implantation of endometrial tissue disseminated by blood escaping into the peritoneal cavity from (1) the menstrual rupture or perforation of an endometrial cavity (cyst), most frequently seen in the ovary, (2) the menstrual

reaction of endometrial tissue growing on the peritoneal surface of the ovary or of other pelvic structures, (3) a back flow, through the Fallopian tubes, from the uterine cavity, and also (4) from the menstrual retraction of the tubal mucosa. Other means of dissemination of endometrium may occur, these include metastatic or embolic spread from fragments of endometrial tissue which at times reach the venous circulation during menstruation from the mucosa lining the corpus uteri and also from ectopic endometrial foci. He is inclined to support the view that differentiation of coelomic epithelium is a source of endometrial tissue in the ovary and peritoneum. Much of Sampson's paper is occupied by criticism of the work of Novak and others who have not agreed with his views on the origin and spread of ectopic endometrium, he admits that sometimes endometrial tissue found microscopically in the lumen of the Fallopian tube has only reached that situation during the preparation of the tissues prior to staining. Proof is adduced that the lumen of the interstitial part of the tube is not too small to allow the passage of endometrial fragments. In two cases coming to operation during a menstrual period, endometrial fragments were found in blood present in the tube, but ingress into the abdominal ostium from pelvic ectopic endometrium could not be excluded. The paper is illustrated by seventy one microphotographs.

#### 602 Transportation of the Ovum along the Fallopian Tubes

F. KOK (*Zentralbl. f. Gynäk.*, October 15th, 1927, p. 2650) believes that peristalsis rather than ciliary movement accounts for the passage of the ovum along the tube and that the tubal movements depend on the ovarian cycle. At ovulation or shortly before it, a definite paralysis of the circular fibres of the whole tube occurs and lasts some days. In spite of this the ovum makes a quick passage to the isthmus portion and considerable difference in activity has been noted in different parts of the tube. This influenced the author to consider the possibility of differences in innervation and sensibility in the ampullary and isthmus portions. Researches as to innervation in small experimental animals led to nothing, and he then tried the reaction of each part to adrenaline and pilocarpine, the latter of which always caused contraction. The effect of adrenaline varied with the time in the ovarian cycle, if fully developed corpora lutea and ripening follicles were present it caused relaxation of the ampulla and a brief relaxation of the isthmus followed by tonic contractions, after extrusion of the ovum the relaxation of the ampulla was transient and quickly followed by tonic contraction, while the isthmus contracted at once. After three or four days the ampulla relaxed, while the isthmus was still contracted. Kok concludes that during these days the tube is ready to contract, especially at the isthmus portion, the ovum probably remains in the isthmus for the days it spends in the tube, and is then propelled into the uterine cavity by strong muscular contractions occurring after the temporary paralysis has passed off. The isthmus contraction may be caused by some adrenaline like substance appearing in the blood during ovulation. It is not known by what means the ovum makes its quick journey through the ampulla. It is not by direct muscular action, as its lumen is too wide for it to act directly on the minute ovum, but it may be by suction.

### Pathology.

#### 603 Action of Bile on the Agglutinating Power of Serum

P. FORMICOLA (*Il Morgagni*, October 16th, 1927, p. 1641), as the result of experiments *in vitro* and on rabbits, found that bile possesses a well marked power to increase the agglutinating capacity of the blood serum. This applies both to the time in which agglutination takes place and the agglutination titre. In the first group of experiments in which immune sera were used agglutination in a hanging drop appeared in the presence of bile in about half the time required when the ordinary saline solution was used. In a second group of experiments the agglutinogenic action of the bile was demonstrated by its increasing by about twenty fold the agglutinating action of certain sera. In a third series of experiments (on rabbits) agglutination in presence of bile always showed the formation of agglutinins in a shorter time than that needed to produce the same phenomenon by using normal saline solution. The difficulty in explaining these results is due to the fact that the mechanisms leading to the agglutination of bacteria flocculation, and subsequent precipitation are not fully understood. The bile, as De Mare has shown, acts on agglutination by its bile salt content—namely, sodium taurocholate and glycocholate. It is probable, therefore, that the action of the bile may be attributed to these salts, but further researches are required to confirm

this hypothesis. As regards the mechanism of the action of the bile salts, two hypotheses may be entertained either they may sensitize the bacteria so as to render them more readily agglutinable, or the physico-chemical changes in the medium may favour the conglomeration of the organisms and their precipitation.

#### 604 A Thermo-resistant Diphtheroid Bacillus in Milk

G. PERONDI (*Lo Sperimentale*, October, 1927, p. 538), in the course of some experiments on the sterilization of milk, encountered a diphtheroid bacillus capable of resisting a temperature of 75° C for three minutes. After being heated, the milk was plated in the usual way, and the resulting colonies studied. Most of them proved to belong to spore bearing organisms of the subtilis or m. sarcinicus groups, but colonies of a heat-resistant staphylococcus—the *Staphylococcus lactis thermophilus* of Patzschke—and of hitherto undescribed diphtheroid bacillus were found. This latter organism was a straight or curved granular bacillus, arranged in V, L, and palisade forms, and presenting clubbed ends. On agar the colonies were punctiform, moist, opaque, and of a bluish colour. On media containing sodium tellurite the colonies were coloured deep brown, due to reduction of the salt. Subcutaneous injection of 2 c.c. of a suspension of an agar culture into a guinea pig was without effect, when the animal was killed ten days later no lesions were found. The thermo resistance of the organism was tested in milk. The author considers that this organism belongs to the pseudo diphtheria group of bacilli, and is similar to those that have been found in the throat, conjunctiva, healthy vagina, skin, normal appendix, faeces of healthy animals, vaccine lymph, milk, cheese, and various pathological products.

#### 605. Non specific Agglutinins in the Blood of Tuberculous Patients

L. SCOLARI (*Giorn. di Batteriol. e Immunol.*, September, 1927, p. 631) has examined the blood serum of 100 patients suffering from pulmonary tuberculosis for the presence of agglutinins to the following organisms: *B. typhosus*, *B. paratyphosus* A and B, *B. dysenteriae* Shiga and Flexner, *V. cholerae*, *B. melitensis*, *B. abortus*, *B. coli*, and *Staphylococcus aureus*. Before use the sera were inactivated by heat at 50° C for half an hour, dilutions were made from 1 in 20 to 1 in 150. Altogether twenty patients were found to have non specific agglutinins in their sera. Eight sera agglutinated Shiga's bacillus, five *B. paratyphosus* B, three *B. paratyphosus* A, two Flexner's bacillus, three the *B. abortus* of Bang, and four the *Staphylococcus aureus*, in five of the twenty patients agglutinins were present to two organisms simultaneously. The author states that agglutinins were more frequent in the blood of febrile than of non febrile patients, and that they occurred more often and were more active in patients whose general condition was good than in those whose general condition was poor. He considers that the frequency of non specific agglutinins in the blood of tuberculous patients is not greater than in that of normal persons, but that when they are present their activation titre was higher than in health. For the practical diagnosis of fevers due to organisms such as those investigated, occurring in the course of tuberculosis, he considers that a higher titre must be reached than is usually considered necessary before the agglutinins can be regarded as specific.

#### 606. Vitamin A Deficiency and Metaplasia

MORI observed metaplasia and other changes in the lining epithelium of the glandular organs in rats fed on a diet deficient in fat soluble vitamins, and these findings were confirmed by Wolbach and Howe. As the diets employed by these experimenters were deficient in several vitamins, H. GOLDBLATT and MARI BENISCHKE (*Journ. Exper. Med.*, November 1st, 1927, p. 699) performed a series of experiments to determine whether a single vitamin deficiency (vitamin A) could induce these changes. In their experiments 63 rats were used which were arranged in three groups, the first received a diet deficient in vitamin A and D, the second one deficient in vitamin A alone, and the third a complete fat deficient diet with cod liver oil added. Of the 26 rats in Group I, 23 showed metaplastic changes in one or more organs, 17 of the 18 Group II animals displayed similar changes, while in the Group III rats none were seen. In the case of 6 rats deprived of food but given adequate amounts of vitamin A, cod liver oil, warmit, and lemon juice, no metaplastic changes occurred. The authors conclude that a dietary deficiency of vitamin A alone is adequate to induce metaplasia of columnar, cuboidal, and transitional epithelia to the squamous, keratinizing type in some organs, and that such metaplasia constitutes a good morphological indicator of the deficiency of this vitamin in the diet. The changes are at least in vitamin A deficiency alone as in deficiency of both vitamins A and D. Inadequate food does not induce metaplasia if the vitamins are supplied.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 607 Insulin and Blood Pressure.

R STRISOWER (*Bull Arch f med Med* October 10th, 1927, p 429) has investigated the fall in blood pressure which occurs after injection of insulin but does not correspond with the diminution in blood sugar. He recognizes three classes of patients: those with hypertension associated with diabetes; those with essential hypertension; and cases of hypertension associated with renal disease. Ten observations in six cases of diabetes showed that the fall in pressure was between 48 and 15 mm Hg. Though there is no definite correlation between this fall and the sugar reduction, a high percentage of blood sugar occurred in hypertensive cases. In seven cases of chronic nephritis the effect of injecting insulin was much less than in the other types of hypertension. The greatest fall in blood pressure amounted to only 2 to 5 per cent, and in these cases the difference between the decrease of action of the pancreatic hormone on blood pressure and on the blood sugar content was greatest. In one case the blood sugar was diminished on two occasions by 33 and 36 mg., although the blood pressure fell only 5 mm Hg. Strisower finds it difficult to explain these phenomena, but he suggests that the action of insulin is directly antagonistic to that of adrenaline, stimulating the vaso-dilator and parasympathetic vaso-constrictor fibres. Other authors think that insulin stimulates the pneumogastric. It is also thought possible that insulin may have some action on cholesterol metabolism and that cholesterolæmia is a cause of hypertension. The author concludes that whatever hypothesis is accepted, the fact remains that insulin has but little effect upon nephritic hypertension. In a greater percentage of cases of pure hypertension a distinct fall in blood pressure occurred. It is probable that the pancreatic hormone has a central action comparable with those of the thyroid and pituitary glands.

### 608 Pseudo appendicular Form of Lethargic Encephalitis

G CAUTIERO (*Stadium* October 20th, 1927, p 374) who records an illustrative case in a man aged 29, remarks that lethargic encephalitis was characterized by Leonomo who first described it, as a capricious disease owing to its polymorphous nature and irregular course. Cautiero's patient was a man aged 29 who was admitted to hospital with severe pain in the right lower abdominal quadrant with tenderness at McBurney's point, and a temperature of 100.6. A diagnosis of appendicitis was made and operation advised but two days later symptoms of encephalitis appeared in the form of persistent insomnia, occipital headache, nuchal rigidity, diplopia, ptosis, strabismus, blurred vision, dysarthria, polyphagia, spasmic convulsions and myoclonic movements. The Wassermann reaction was negative in the blood and in the cerebrospinal fluid which was clear and under tension. The symptoms gradually subsided, and at the end of three months the patient appeared to have completely recovered. Cautiero attributes the abdominal symptoms to involvement of the nerve roots and peripheral nerves by the virus of lethargic encephalitis.

### 609 Poisoning by Barbitone Derivatives.

DAPGEN and DORE (*Bull et M Soc Med des Hop de Paris*, October 27th, 1927, p 1332) report a case of acute central poisoning followed by recovery. A man aged 25 was admitted to hospital in a comatose condition with generalized convulsions but no stertor. He had taken approximately 27 grams of diethylal about twelve hours previously. The neck was flexed by contracture of both sterno-mastoids. The corneal reflex was present and the pupils were slightly dilated, reaction well to light. The tendon reflexes were brisk, ankle clonus was greater on the right side, the plantar reflex was flexor. Cutaneous reflexes were absent. There was retention of urine, a catheter specimen was normal. The cerebrospinal fluid was normal. On the following morning, there were contractions of the limbs and trismus followed by convulsions with opisthotonus. The patient then fell into a deep sleep but in the afternoon he awoke for fifteen minutes and answered questions rationally. He then slept for fourteen hours, the retention of urine and trismus persisted. Next morning, he awoke as if from normal sleep and his memory was clear. The improvement continued except for left hemiparesis and earache, there was no sign of labyrinthine disturbance. He was discharged cured a few

days later. The authors refer to another patient who recovered after a large dose of diethylal, and also to a patient who took about 71 grams of the drug with fatal consequences. In a fourth case a man aged 36 swallowed 5 grams of veronal and 1 gram of diethylal. Half an hour later he was deeply comatose, and camphor, strychnine, and oxygen produced no change. Next day all the limbs were flaccid, the temperature rose to 106° and the respirations were 52. All reflexes were absent and the extremities were cyanosed. The pupils were contracted and there was corneal anaesthesia and enuresis. The heart sounds were weak and rapid, the cerebrospinal fluid was normal. The patient died twenty-four hours after taking the drugs. At the necropsy generalized congestion of the central nervous system was found, especially of the meninges with discrete haemorrhages throughout the brain. There was consolidation of the lower lobe of the right lung. Crystals of both drugs were recovered from all the internal organs and veronal from the cerebrospinal fluid. Veronal predominated in all the organs examined, and the authors conclude that diethylal played only a secondary part in the poisoning. They cannot explain the rapid rise of temperature, apart from the extensive consolidation of the lung.

### 610 Epidemiology of Typhoid Fever in Country Districts

D G GILL (*Journ Amer Med Assoc* October 8th, 1927, p 1193) remarks that though typhoid fever has been steadily decreasing throughout the United States it is still a major problem in the Southern States. Most of the cases are found in the small towns and strictly rural districts. The highest rates occur in towns with populations under 1,000, while 80 per cent of the typhoid occurs in rural areas and towns with populations up to 5,000. The causes for the high incidence of the disease are said to be defective sanitation and water supplies, and the large number of typhoid carriers. Gill thinks that approximately 10 per cent of those who have had an attack of typhoid fever become permanent carriers, and are probably the source of most rural typhoid.

## Surgery.

### 611 Acute Haematophorphyria.

H KUTZEN and R BECKER (*Deut Zeit f Chir*, November, 1927, p 332) who record an illustrative case state that haematophorphyria is a form of auto-intoxication by haemato porphyria which is closely allied to blood pigment and may occur normally in small quantities in human excreta. The acute attack of haematophorphyria sets in suddenly with extremely violent colicky pain and vomiting and more or less marked and persistent constipation. The colicky pains are caused by spasms which appear to be chiefly localized in the duodenum and uppermost part of the ileum while the segment of the intestine above and the stomach are dilated. The pain is usually localized in the right hypochondrium or in the middle line between the xiphisternum and the umbilicus but it is frequently found in the right iliac fossa, or radiates diffusely into the hypogastrium, left hypochondrium or back. The diagnosis at this stage is usually colicystitis, gastric disease, appendicitis, pancreatitis, intestinal obstruction, or renal or ureteric disease. The vomit consists of mucus mixed with bile. Fever is absent or very slight. In contrast with acute inflammatory affections of the abdominal organs reflex distension is almost completely absent. On the day following the attack or on the same day the urine assumes a dark porphyria colour with distinct fluorescence and the correct diagnosis is then usually made. The attack may last for several hours or even days. A single attack or a series of attacks may be followed by long intervals of complete health so that the prognosis at this stage is relatively favourable. On the other hand the appearance of nervous symptoms, such as paresthesia, hyperaesthesia, neuralgia and paralysis, is a very grave sign, and in 50 per cent of such cases death ensues with symptoms of rapidly ascending paralysis. In most cases the course of the disease is very protracted but some cases run a fulminating course, death occurring in a few days. The author's patient was a man aged 59 in whom haematophorphyria was associated with haemochromatosis, cirrhosis of the liver and carcinoma of the pancreas, with metastases in the liver. The case was thus closely allied with the group of symptomatic haematophorphyria, but differed from it (1) by

the attacks resembling recto haematemphrynia clinically, (2) by the excretion of haematemphrynia occurring not only in the urine, but also in abnormally large quantities in the faeces, and perhaps also by (3) slight indications of hyper-sensitiveness to light.

#### 612 Avulsion of the Diaphragm

W A BRYAN (*Surg, Gynecol and Obstet*, November, 1927, p 688) reports the case of a man, aged 40, who, as the result of a traffic accident, suffered from avulsion of the diaphragm, followed by the passage of the stomach, omentum, and part of the large and small intestine into the chest. The diaphragm was torn from its attachment to the left chest wall for a distance of about ten inches, the free portion bending round the oesophagus and permitting swallowing, though vomiting was prevented. An anaesthetic was given, the viscera were returned to the abdomen, and the diaphragm was attached to the chest wall by through and through mattress sutures of catgut, but the patient died before removal from the operation table. Bryan discusses this unusual type of injury and doubts whether the artificial union of the diaphragm with the chest wall would have been sufficiently secure to withstand the tension imposed by coughing, sneezing, or heavy straining. He believes that the injury was caused in the following way: the lung were filled with air, and, in anticipation of the impending compression between two vehicles, the man braced himself by tightening all the muscles of the body, including the diaphragm, which was torn from its attachment in consequence of the combination of traction, fixation, and shearing by the lower lobe of the compressed lung.

#### 613 Fistula as a Complication of Peptic Ulcer

R T MONROE (*Amer Journ Med Sci*, November, 1927, p 599) reports a case showing a very rare complication of peptic ulcer—namely, a fistulous tract between the stomach and duodenum caused by the perforation of a chronic gastric ulcer. Only ten similar cases have been recorded, and those, according to Welch, demonstrate that gastro-duodenal fistulae are more frequent with the third part of the duodenum than with the first. In a review of the literature Monroe shows that the most common fistula due to peptic ulcer is the gastro-colic, though the ulcer may perforate other portions of the intestinal tract as the jejunum and ileum. Welch has recorded fistulae between the stomach and gall bladder, and between the stomach and common bile or pancreatic ducts. Cases of perforation into the heart, pericardium, and portal vein, as well as of gastro-cutaneous and gastro-pulmonary fistulae, have also been reported. On the case now reported a cheiro-ectomy had been performed in 1919, and a diagnosis of chronic gastric ulcer then made. For six years the patient was free from distress, but symptoms then arising she returned to hospital for further treatment, when a gastro-intestinal radiological investigation revealed the presence of the fistula. The treatment given was rest in bed, small meals, and small doses of alkali. Cancer was thought improbable, and surgical intervention deemed unnecessary. The patient was discharged with the advice to take five small meals daily, and alkali occasionally for any distress. A month later she was symptom free and gaining weight. Monroe maintains that fistulae between the stomach and other internal organs of the body surface, though rare, are sufficiently common to warrant more notice than they have hitherto received, and calls attention to the increase in gastro-colic fistulae since the introduction of gastro-enterostomy as a treatment for gastric ulcer.

#### 614 Omental Volvulus

E TROJAN (*Zentralbl f Chir*, October 22nd, 1927, p 2705) refers to the rarity of intra-abdominal omental volvulus. Among 158 collected cases, 140 occurred in a hernial sac, while only 18 (8.7 per cent) were intra-abdominal. Trojan's case was of the latter type, and the symptoms resembled those of acute appendicitis. A man, aged 24, was admitted to hospital with a definitely tender resistant swelling, as large as a fist, in the region of McBurney's point. The temperature was 100°, the pulse 120 and the leucocyte count 12,700. The probability of appendicitis was considered, although the extent of the swelling after twenty-four hours' duration was against this, as also was the fact that the patient had never before had symptoms of appendicitis. Two years previously, when engaged in gymnastics, he had discovered a swelling, the size of a hazel nut, in the right groin which disappeared on pressure and did not recur after further exercise. On opening the abdomen a little blood-stained serous fluid appeared. The swollen omentum was deep red, with bluish patches, but did not resemble the appearance of the omentum in a case of appendicular abscess. After slitting off the general peritoneal cavity with swabs, the omentum was brought forward, exposing the appendix, which lay free in the peritoneal

cavity although its apex was loosely adherent to the parietal peritoneum. The swollen inflamed right half of the omentum depended from a pedicle 3 cm in thickness which had been rotated through 360 degrees upon its axis. An incision measuring 20 by 7 cm showed suppurative and necrotic changes. The omental pedicle was clamped and divided and the appendix was removed on account of its typical adhesion. Recovery was uneventful. Trojan states that omental volvulus occurs most frequently in obese patients between the ages of 35 and 55. When it is intra-abdominal it may simulate cholecystitis, or appendicitis as in the present case. If an omental volvulus complicates hernia it may resemble internal herniation or adhesions in the hernial sac, while, when the volvulus is actually in the hernial sac, it may simulate iliac,

## Therapeutics.

#### 615 Quinidine in Ectopic Rhythms

C W BARRIER (*Journ Amer Med Assoc*, September 3rd, 1927, p 742) considers that the dangers of quinidine have been exaggerated and that it is a useful remedy in all cardiac arrhythmias produced by eicetus movement. It acts upon the heart by mildly paralyzing the vagus, lowering the rate of sinus impulse discharge, slightly decreasing auriculo-ventricular conduction, lengthening the refractory period of ventricular muscle, slowing its conduction, and lessening its excitability. Its therapeutic use depends upon its effect on eicetus movement, which it abolishes, and since such movement is the basis of all the arrhythmias quinidine has a theoretical value in their treatment. It is most useful in paroxysmal and transient auricular fibrillation and also in chronic auricular fibrillation, the groups with initial fibrillation usually responding better than those with sclerotic fibrillation, patients with small hearts better than those with large hearts, and those who show coarse auricular waves better than those with fine waves. Idiosyncrasy should be tested by giving two 2-grain doses on the first day, three 6-grain doses on the second day, and increasing one dose a day until five doses of 6 grains are being given. Normal rhythm should ensue on the fifth day. Since the drug is rapidly excreted frequent small doses are better than large doses at longer intervals, and it should be continued at the minimal daily amount found necessary for continuing a normal mechanism for each individual patient. In selecting cases a competent myocardium is the criterion, and its use is contraindicated in the aged and in patients with marked hypertrophy, chronic heart failure, active endocarditis, or significant changes in the T waves or Q R S complexes of the electrocardiogram. The dangers attending its use are respiratory paralysis, embolism, induction of ventricular tachycardia and fibrillation, failure of the sino-auricular node to function when eicetus movement is abolished, and the production of auricular ventricular block with depression of stimulus production below the block. Cases of auricular flutter, premature contraction, and paroxysmal tachycardia have also been benefited by the drug.

#### 616 Treatment of Impotence in the Male

C JUARROS (*Arch de med, cir y esp*, November 5th, 1927, p 539), who remarks that male impotence is very frequent in Spain, probably as the result of masturbation, maintains that the treatment should always be made dependent on the cause of the condition, and that the routine prescription of aphrodisiacs is bound to end in failure. Success in treatment in the most favourable cases merely amounts to an action of reinforcement, even in sexual debility, which constitutes the first stage, the results do not merit any higher qualification. Juarros believes that cases of pure or psychical impotence do not exist: they are always the consequence of other conditions, whether local such as gonorrhoea, or general such as diabetes. Opotherapy is only likely to be of service when the impotence is due to endocrine disturbance such as hypothyroidism, in other cases it is disappointing. Other drugs act only as transient stimuli, they may solve the problem of the moment but do not effect a complete cure. The results obtained from electrical treatment do not justify its employment. Steinach's method seems to have more effect on the patient's general condition than on his potency. Psychotherapy is an excellent adjunct, but nothing more.

#### 617 Treatment of Typhoid Fever

W S MAGILL (*Med Journ and Record*, November 2nd, 1927, p 546) recommends that as soon as the diagnosis of typhoid fever is made an intravenous injection of 10 c cm of a 1 per cent solution of mercurochrome (220 soluble) should be given, preferably in the morning, with an empty stomach. It should be followed in twenty-four hours with a second injection of 20 c cm or less of the same solution if the reaction is severe.

Twenty four hours later a third injection of 30 c cm should be given subject to the previous degree of reaction in each case and provided that there is no evident salivation. Blood should then be transfused up to 300 c cm from a carefully selected donor, who may or may not have been immunized twenty four hours previously with the usual first dose of typhoid vaccine. The injection should be stopped at the first sign of reaction in the patient, since even such small amounts as 20 to 30 c cm of blood often cause considerable improvement. Blood count control is a valuable aid in determining the opportunity and time for successive transfusions, which should be continued until complete convalescence is assured. If immunized blood is used a new donor, vaccinated within the previous twenty four hours, should be taken for each injection.

#### 618. Hexamine in Malaria.

E. OLIVERA (*Arch de med. ex. y. esp.*, November 12th, 1927, p. 566) remarks that though quinine and its salts form the specific treatment of malaria the problem of prophylaxis and treatment of this troublesome disease cannot be regarded as settled. The extraordinary tendency of the benign tertiary infection to relapse, the malignancy and resistance to quinine salts of the parasites of the Laveran type the severe pernicious forms in some of which, such as haemoglobinuric fever, quinine is absolutely contraindicated as well as the not infrequent cases of quinine intolerance and the scarcity and high cost of the drug are all reasons for looking for substitutes or adjuncts for quinine treatment. Since 1925 Olivera has employed hexamine in the treatment of malaria giving 5 to 10 c cm by intravenous injection. Of 47 cases so treated, some recovered after four or six injections. Others, though showing some improvement proved more refractory to this treatment, and some were clinically cured although examination of the blood showed the presence of the parasites after an intensive treatment. Hexamine is said to be especially indicated in the pernicious forms and especially in haemoglobinuric fever in malaria complicated, pregnancy and in cases of intolerance to quinine salts. Moreover, in combination with quinine it has the twofold effect of acting on the parasites and favouring the elimination of toxins.

## Radiology

#### 619. X ray Treatment of Tuberculous Glands.

H. MARKUS (*Deut. Zeit. f. Chir.*, September 1927, p. 209) records his observations on 320 cases of tuberculous glands of the neck treated by x rays. 45.3 per cent were in males and 54.7 per cent in females. The age groups were as follows: first decennium 13.2 per cent, second decennium 36.5 per cent, third decennium 28 per cent, fourth decennium 8.5 per cent, fifth decennium 6 per cent, sixth decennium 2.1 per cent, seventh decennium 0.3 per cent. 46.4 per cent of the patients were between the ages of 15 and 25 years. A cure was effected in 93.9 per cent but a relatively large number of complications were observed. The most frequent was chronic oedema of the skin to which the term "plaques" was applied of this 11 examples occurred. All these cases as well as some others, 19 in all showed more or less marked telangiectases, which appeared from three months to two years after the application of the rays. In one case rapid development of caries of hitherto healthy teeth occurred. Only one other example of this sequel of x ray treatment of tuberculous glands of the neck reported by Gotthardt has been recorded. In another case irradiation was followed by complete aphonia due to paralysis of the left recurrent laryngeal nerve recovery ensued in about a year. The paralysis was probably due to the pressure on the nerve by growth of connective tissue caused by the irradiation.

#### 620. Radium Treatment of Carcinoma of the Rectum.

H. H. BOWING (*Radiology*, September, 1927, p. 179) describes the treatment of carcinoma of the rectum by radium and gives full notes of its use in four typical early and operable cases. Though too few for statistical purposes these cases were representative of the small localized and operable lesions. Bowing states that care must be taken to deliver a therapeutic dose and to avoid the possibility of irradiation proctitis. In one case the interstitial method of placing a uniform dose in the malignant area was employed. Bowing remarks that although colostomy is desirable because it places the field of treatment at rest and allows of greater cleanliness being maintained, thus minimizing the risk of secondary infection, this operation, with the chance of losing sphincter control, terrifies many patients. Adequate exposure for direct vision with the proctoscope is essential, and the use of the endoscopes enables accurate application and maintain-

ance *in situ* of the radium tube, the rectal lumen being packed with vaseline gauze, which is, as a rule well tolerated by the patient. Probably four hours is sufficient for treatment, this depends on the thickness of the lesion and the filters employed. Those indicated are 1 mm of brass and 2 mm of aluminium or Para rubber. By using the broken dose method, with an interval of three or four days between applications, the individual response can be estimated. At each application the normal rectal walls should be packed away from the applicator as much as possible. Repeated proctoscopic examinations are advised during treatment and at frequent intervals afterwards for several years.

#### 621. Ammonium Bromide in Urinary Radiology.

WHILE recognizing with Wedd the efficacy of sodium bromide in urinary radiology, W. E. COULTS (*Journal of Urology*, October, 1927, p. 296) prefers ammonium bromide for this work, as the shadows produced by the latter are much more opaque than those by the bromide of either sodium or strontium. It has been shown that ammonium bromide when injected into the bladder or renal pelvis, absorbs a greater proportion of the x rays than do the sodium or strontium salts, consequently the plate gives a more precise image of the urinary tree. This greater opacity is due to the fact that the ammonium salt contains a greater proportion of bromine (81.6 per cent) than does the sodium salt (57.52 per cent). Ammonium bromide, or ammonia bromhydrate is a white crystalline powder composed of small cubical or prismatic crystals, which is colourless when obtained by slow evaporation. On exposure to the air and on heating, in aqueous solutions, it becomes yellowish and gives an acid reaction. In 15 parts of water the salt dissolves with great heat absorption. The acidity of aqueous solutions is due to a hydrolytic decomposition and these solutions should be kept in dark bottles to prevent the liberation of the bromine. With urine no precipitate is formed. The pharmacological properties of the ammonium compound are greater than those of the sodium and potassium salts, as both the bromine and the ammonium exercise their effects and Gibb has shown that it lessens the sensibility of mucous membrane. Coultis employs this salt in urinary radiology in sterilized 25 per cent aqueous or glycerin solutions. After the injections the ureter pelvis, or bladder is washed with sterile water. The after effects of injections of ammonium bromide are similar to those of the sodium salt noted by Wedd.

#### 622. X ray Examination in Sciatica.

ACCORDING to V. BARTOS (*Bratislavské Lekárske Listy*, August, 1927, p. 82) the clinical symptoms of sciatica, including Lasègue's sign, diminished patellar and Achilles reflexes and wasting, may be present not only in diseases of the lumbar spine in sacralization of the lumbar vertebrae, and in arthritic changes of the sacro-iliac joint, but may also be observed in ossifications of the ilio-lumbar ligament, in arthritic involvement of the superior processes of the ilio-sacral column, and in thoracic spina bifida. These observations indicate how different pathological entities may give rise to the clinical appearance of sciatica and emphasize the importance of x ray examination in this disease.

## Obstetrics and Gynaecology.

#### 623. Puncture of the Pouch of Douglas.

B. ZONDER and W. KNOOR (*Zentralblatt f. Gyna.*, November 5th 1927, p. 2342) summarize as follows the information which may be gained by aspiration with a syringe introduced in the pouch of Douglas through the posterior vaginal fornix. Fluid blood in smaller amounts than 5 c cm may come from a blood vessel (in which case the erythrocytes in the deposit will not show deformity) and has no diagnostic significance when at least 5 to 10 c cm can be drawn off this comes from a haemorrhagic or from a corpus luteum cyst, intact, or ruptured. Admixture of blood with small clots points to extrauterine gestation. Thin comparatively clear reddish brown fluid, of low specific gravity, suggests strongly a twisted ovarian cyst. The authors have verified this by operation in three cases in one of which the history and clinical signs were those of ruptured ectopic pregnancy. A thick mucous fluid is typical of pseudo-mucinous cystoma. Aspiration on account of the consistency of the fluid may be difficult or impossible. The interpretation of a thick or thin serous fluid is more complicated and the protein content should be roughly estimated by Rivalta's method. The contents of the syringe being allowed to fall drop by drop into dilute acetic acid, richness in protein denotes an acute inflammatory process and poverty points to a cyst. Fluid resembling blood serum in appearance and consistency may be drawn off from a chronic inflammatory exudate or from an ovarian follicular cyst. In the

former case the sedimentation time of the erythrocytes is diminished. For the diagnosis of the later follicular cysts the ingenious suggestion is offered of examining by the Allen and Boisy method the ovarian hormone content of the aspirated fluid, oestrius in a castrated mouse injected during the course of forty eight hours with six doses of from 0.1 to 0.3 c.c. denotes the presence of the hormone. In a patient aged 19, whose history and clinical signs suggested ruptured ectopic pregnancy, ovarian hormone was found in the fluid obtained after puncture of the pouch of Douglas, an operation was avoided, and cure followed aspiration. The significance of the presence of pus is obvious. Zondek and Knorr do not recommend diagnostic puncture of the pouch of Douglas except in cases in which, after careful consideration of the history, physical findings, and red blood cell sedimentation time, the diagnosis still remains obscure. It is essential, of course, that previous palpation shall have demonstrated quite clearly a definite tumour, aspiration of which seems feasible. During the last four years they have punctured the pouch of Douglas in 85 cases in which diagnosis was obscure, these constituting 4.6 per cent of the cases seen in that period. No inconvenience or untoward consequences followed the procedure, even when subsequent operation was delayed for twenty one hours. A curved needle of the same lumen as a lumbar puncture needle is used, after disinfection of the vagina with alcohol or tincture of iodine. In cases of ruptured ectopic gestation coming to operation after puncture of the pouch of Douglas, drainage through the posterior fornix is considered advisable. In all save one of the authors' 85 cases correct diagnosis was arrived at after the puncture, and in several instances laparotomy was thereby avoided, among others, 16 cases of supposed ectopic gestation were recognized as cases of inflammatory tumour, and 8 cases of suspected adnexal tumour came to be correctly interpreted as examples of ruptured tubal pregnancy.

#### 624 Indications for Caesarean Section

G. C. MOSHLER (*Surg., Gynecol. and Obstet.*, November, 1927, p. 655) discusses the circumstances under which Caesarean section is justified, and concludes that a positive indication is furnished by a tumour blocking the pelvic outlet, or an ovarian conjugate diameter of less than 17 cm. and a true conjugate of no more than 6 cm. He believes that 75 per cent of all pelvic contractions allow delivery by the natural passages. In the classical conservative operation the maternal mortality should, he thinks, not exceed 2 per cent, but this is increased considerably by rupture of the membranes, attempts to use forceps, induction, version, craniotomy, or even repeated vaginal examinations prior to the section. After any of these have occurred, Mosher states that craniotomy should be selected in the interest of the mother's life. If the operation is to be performed after potential infection it should take the form of Poirs' procedure, or of a low extraperitoneal modification. In caesarean section is limited to the case of the primipara with rigid, long, unyielding cervix, no improvement having followed conservative treatment for six hours. He thinks that placenta praevia is best treated, as a rule, by induction with a Voorhes bag, the exception being severe bleeding without dilatation in the central type of placental attachment.

#### 625 Antisepsis in the Induction of Labour

H. W. MALLS (*Journ. Amer. Med. Assoc.*, November 12th, 1927, p. 1685) refers to the danger of infection when a hydropneumatic bag is used for the induction of labour, and states that the risk is considerably lessened by the routine use of a 4 per cent solution of mercurochrome (220 soluble) as a vaginal antiseptic before the introduction of the bag. In ninety three inductions without the use of mercurochrome the morbidity was 29 per cent, whereas in seventy eight in which this antiseptic was employed the morbidity fell to 11.5 per cent. Similarly, in toxæmic cases it was reduced from 20.5 to 10.3 per cent. Without the bag was in the uterus, whereas increased with the time the bag was in the uterus, whereas in the mercurochrome group the reverse was the case.

### Pathology.

#### The Synergism of Antibodies

626 M. WEINBERG and J. BAROTTE (*C. R. Soc. de Biologie*, November 18th, 1927, p. 1326) have noticed that the agglutination titre of a serum which is both antitoxic and antimicrobial varies according to whether it is tested with a diluted culture or with organisms which have been centrifuged and suspended in saline. Working chiefly with anti-*perfringens* serum they find that when the results are

recorded after four hours' incubation at 37°C the titre with the diluted culture is higher than with the washed suspension of centrifuged organisms—sometimes as much as 1 in 1,000. In looking for the explanation of this phenomenon they observed that the difference between the two antigenic dis- appeared if increasing doses of a serum is higher when 'suspension of centrifuged organisms. From this they con- clude that the agglutinating power of a serum is higher when it is tested against an antigen containing the soluble culture products, the reason being that the agglutinins are reinforced by the precipitins. If precipitins can be able to reinforce the action of precipitins. This they find to be true. Certain samples of antitoxic anti-*perfringens* serum are able to cause flocculation only when large quantities of the corresponding toxin are added, and then only of slight degree. But if a very small amount of centrifuged organisms is added to the mixture—so small that they do not modify the limpidity—good flocculation is obtained, even in mixtures containing only one tenth of the amount of serum. This reinforcing action of one antibody by another they term "synergism". In another paper (*ibid.*, p. 1328) the authors report that it is extremely difficult to distinguish between antitoxic and antimicrobial serums. Working with anti-*perfringens* and anti-septic serum they observed that an antitoxic serum prepared with filtered toxin often had a high agglutinating titre to its homologous organism—as high as 1 in 5,000 or 1 in 10,000. The reverse was also true, an agglutinating serum prepared with dried formalized or with washed living organisms was often antitoxic, neutralizing, for example, a lethal dose of toxin with one two hundredth of serum. It is concluded that there is in fact no sharp distinction between the two classes of serum, the bacterial bodies always contain a small amount of toxin, which gives rise to injection to antitoxin, and filtered toxins contain some of the products of microbial disintegration, which produce agglutinins.

#### 627 Excretion of Chlorides in Hepatic Disease.

B. KRASS and L. POLLAK (*Wien. klin. Woch.*, October 6th, 1927, p. 1251) found as a result of a series of observations on the effect of sodium chloride, potassium chloride, and ammonium chloride on the excretion of chlorides in a number of normal persons and of patients suffering from catarrhal jaundice and other conditions, that the excretion of chloride ion depended to a variable extent on the nature of the given along with it. In healthy persons the excretion of chloride was little affected by the nature of the kation administered, though there was some tendency to chloride retention when the sodium salt was given. In patients with hepatic disturbance or oedema there was marked retention of chlorides when the kation was sodium, but good excretion when potassium chloride or ammonium chloride was administered. The authors state that it is now generally recognized that a diffuse parenchymatous lesion of the liver is present in catarrhal jaundice. In the febrile patients examined marked retention of chlorides occurred irrespective of the kation. As the alterations in chloride excretion were similar in patients with hepatic disease and in those with oedema of renal or hepatic origin, it is suggested that put at least of the effect of the sodium ion is produced through the oedematous or congested liver. The recorded results also indicate that the salt intake of patients with diffuse hepatic disease may be of therapeutic importance and that the administration of potassium salts might be of value, especially as the experimental doses of potassium and ammonium chlorides were in a few cases of jaundice immediately followed by a diminution of the icterus and of pigment excretion in the urine.

628 Diastase in the Blood Serum and in the Urine  
C. K. SCHAANING (*Norsk. Mag. f. Lægevidenskab*, October, 1927, p. 801) investigated the diastase in the blood serum and in the urine of normal individuals and of patients suffering from various kidney diseases. He found that the power of the kidney to concentrate diastase was reduced in cases of enuric kidney, chronic nephritis, hypertension with albuminuria, and diminished renal function, some cases of acute nephritis, and most frequently in the albuminuria of pregnancy. The power to concentrate diastase was also found to be low in two cases of nephrosis with reduced renal function, while in one patient with normal function the concentration power was normal. Some cases of surgical kidney also showed a reduced concentration power. In ten cases the excretion of diastase was lower from the diseased than from the normal kidney. Schaaning concludes that determination of the power of the kidney to concentrate diastase affords a good idea of the renal function in relative agreement with the ordinary kidney function tests.

## British Medical Association

### CURRENT NOTES

#### Medical Appointments Abroad.

THE head office of the British Medical Association has a good deal of information placed at its disposal by its Branches overseas, which may be very useful to those proposing to accept medical appointments abroad. Practitioners are cordially invited to apply to the Medical Secretary B.M.A. House, Tavistock Square W.C.1 for any information that may be available regarding overseas appointments in which they may be interested.

#### Registration of Stillbirths.

THE Ministry of Health has now issued to local supervising authorities under the Midwives Act a circular (No. 802) with reference to that part of the Births and Deaths Registration Act, 1926, which concerns stillbirths. The circular sets out the requirements of the Act in this connexion and in this respect corresponds to the relevant paragraph of the article published in the JOURNAL of June 18th (p. 1118). There are three points in the circular, however, which are worthy of notice. The first is the slight, but only possible, effort made to lessen the dangers of improper practices to which attention was directed in our article by reason of the definition of a stillbirth and of the fact that in certain circumstances such birth can be registered without a certificate. The Minister points out that it is obviously undesirable that the stillbirth should be registered on the relatives' declaration only and requests the local supervising authority to insist on midwives giving the prescribed certificate in all cases they attend if no such certificate is being given by a registered medical practitioner and requests also the maternity and child welfare authority to assist registrars by making inquiries in cases in which a stillbirth has been reported without any such certificate. Presumably the registrar will ask for such inquiries to be made in all the cases. The other points are (1) that if a child whatever the period of pregnancy (even less than twenty-eight weeks), breathes or shows any other signs of life after complete expulsion from the mother and then dies within however brief a period after birth both the birth and the death must be registered and (2) that the giving of a certificate of a stillbirth does not relieve either the midwife or the medical practitioner of such duties as fall upon them under the Notification of Births Act.

#### Treasurer's Cup Golf Competition

The following are the winners of the first (or Divisional) stage of the Treasurer's Cup golf competition.

Tyrishire—Dr W. B. Wilson  
 Bath—Dr R. Waterhouse  
 Belfast—Dr S. R. Hunter

 Norwich—Dr E. W. Everett  
 Nottingham—Dr W. T. Williamson  
 Penzance and Tamar—Dr R. Francis Jones  
 Oxford—Dr G. R. Girdlestone  
 Plymouth—Dr D. O. Twining  
 Reading—Dr A. N. Hooper  
 Potherham—Dr H. R. Filhott  
 Sheffield—Dr J. P. Chalmers  
 Shropshire and Mid Wales—Dr J. Lavelle  
 South Essex—Dr F. Pees  
 South Suffolk—Lieut. Colonel H. E. Staddon F.A.M.C. (ret.)  
 South West Essex—Dr R. G. B. Marsh  
 Striford—Dr J. H. Bletsoe  
 Wandsworth—Dr W. D. McMurtry  
 Westminster and Holborn—Dr F. Howard Humphris  
 West Suffolk—Dr E. C. T. Clouston  
 Wiltshire—Dr W. McElroy  
 Winchester—Dr L. W. Oliver

The final stage of the competition will be played at Cullane No. 1, Edinburgh, on Friday, July 22nd, commencing at 2 p.m. during the Annual Meeting of the Association. The handicap allowed for the final stage will be the lowest handicap of the competitor as at July 22nd.

**Some Effects of the Coroners (Amendment) Act 1926**

Several letters have reached the Medical Secretary lately which indicate that the present position of medical officials at hospitals and institutions in regard to their right to receive fees for performing *post-mortem* examinations and attending at inquests, under the provisions of the Coroners (Amendment) Act, 1926, is not quite clear. Under the Coroners Act of 1887, Section 22 provided that where an inquest was held on the body of a person who had died in a county or other lunatic asylum or in a public hospital, infirmary, or other medical institution, whether supported by endowment or by voluntary subscriptions, the medical officer whose duty it might have been to attend the deceased person as medical officer of such institution was not entitled to a fee. Over many years the Association repeatedly tried to remedy this injustice, and finally Section 22 was repealed by the Coroners (Amendment) Act of 1926. The fees are therefore now payable to those doctors who were excluded by the provision of Section 22 of the Act of 1887. A case has, however, been reported in which a coroner refused to pay a fee to a whole-time medical officer in a county institution on the ground that the county council, which is responsible for the payment of fees to medical witnesses under the Coroners Act, should not be expected to pay the medical officer who was in its whole-time employment for work done during his ordinary working hours. This is a matter between the county council and its employees. The county council may demand that any fees received should be refunded, but it is the duty of all officers concerned to demand the payment from the coroner as a matter of principle. Several curious complaints have already reached the Medical Secretary. In one case a doctor was tendered half the usual fee on the grounds that he had not been detained at the inquest for more than half a day. There is no justification whatever for the payment of anything less than the full fee. Again, a county council is reported to have cut down travelling allowances previously paid to medical witnesses on the ground that the inquest fees had been raised. In one case the net result was that the doctor was paid 5s. less than he would have been paid if the fees had never been raised. The Division concerned has been advised to make representations in the proper quarter.

**Association Notices.****NOTICE OF ANNUAL GENERAL MEETING****NOTICE CONVENING MEETING**

NOTICE IS HEREBY GIVEN that the Annual General Meeting of the British Medical Association will be held in the McEwan Hall, The University, Edinburgh, on Tuesday, July 19th, 1927 at 2 p.m. Business: (1) Minutes of last Meeting, (2) Appointment of Auditors, (3) Report of Election of President for 1928-29.

ALFRED COX,  
Medical Secretary

L. FERRIS SCOTT,  
Financial Secretary and  
Business Manager

**LEICESTER AND RUTLAND AND NUNEATON AND TAMWORTH DIVISIONS**

NOTICE is hereby given to all concerned of the following proposal made by the Nuneaton and Tamworth Division:

That the Civil Parish of Appleby Magna, in Ashby de la Zouche Rural District, be transferred from the Leicester and Rutland Division of the Midland Branch to the Nuneaton and Tamworth Division of the Birmingham Branch.

Written notice of the proposal has been given to the Leicester and Rutland Division and to the Birmingham and Midland Branches, and the matter will be determined in due course by the Council of the Association. Any member affected by the proposed change, and objecting thereto, is requested to write, giving reasons, to the Medical Secretary, British Medical Association House, Tavistock Square, London, W.C.1, not later than August 2nd, 1927.

ALFRED COX, Medical Secretary.

**BRANCH AND DIVISION MEETINGS TO BE HELD**

**BORDER COUNTIES BRANCH**—The annual meeting of the Border Counties Branch will be held at the Crown and Mitre Hotel, Carlisle, on Friday, July 8th at 4 p.m. The Branch Council will meet at 3.30 p.m. Agenda: Branch Council's report and financial statement, report of the election of office bearers for 1927-28. Dr J. R. Burnett will give his presidential address, entitled "Some notes on the history and work of the St. John Ambulance Association." Tea at the kind invitation of the president.

**CAMBRIDGE AND HUNTINGDON BRANCH**—A meeting of the Cambridge and Huntingdon Branch will be held at Addenbrooke's Hospital on Friday, July 8th at 2.30 p.m. Agenda: The Cambridgeshire Branch Council's report and financial statement, report of the past, by Dr W. M. Palmer, disease, by Dr G. Wolf.

**DORSET AND WEST HANTS BRANCH BOURNEMOUTH DIVISION**—The summer social meeting of the Division will be held on Saturday, July 2nd, at Palace House, Bournemouth by kind permission of Lord Montagu of Beaulieu. Members will arrive at Palace House at about 3.30 p.m., and after being shown over the house and grounds will find tea awaiting them at the Montagu Arms Hotel. Each member may take one guest.

**EAST YORK AND NORTH LINCOLN BRANCH**—The seventy-first annual meeting of the East York and North Lincoln Branch will be held on Friday, July 8th when Dr Frank Eve, the president elect, will be installed as president.

**METROPOLITAN COUNTIES BRANCH CITY DIVISION**—A meeting of the City Division will be held at the Metropolitan Hospital, Kingsland Road, E., on Tuesday, July 5th at 9.30 p.m. Dr T. H. G. Shore, curator of the museum St. Bartholomew's Hospital will give a demonstration of pathological specimens with clinical notes. A clinical meeting arranged by the consulting staff will be held at the Children's Hospital, Fickeny Road, on Wednesday, July 6th, at 4 p.m. Tea will be provided. A clinical afternoon will take place at the Metropolitan Hospital on Friday, July 8th, at 4.15, tea at 4 p.m.

**METROPOLITAN COUNTIES BRANCH KENSINGTON DIVISION**—A clinical meeting of the Kensington Division will be held at the Paddington Hospital (Infirmary), Harrow Road, on Thursday, July 7th at 4 p.m. Agenda: Presentation of silver cup to Dr A. I. Cronin, winner of the Kensington Divisional Competition in the Tri-ners Cup golf competition, cases will be shown and demonstrated by Dr Bendle (medical superintendent) and the staff. It is hoped that members will make a special effort to attend. Tea at 4 o'clock.

**MIDLAND BRANCH**—The annual meeting of the Midland Branch will be held at 64, St. James Street, Nottingham on Monday, July 11th, at 3 p.m. Agenda: Correspondence, election of officers, and of public health service representatives on Branch Council, and of Branch Council. An address will be given by the president, Dr W. T. Rowe, M.C., on encephalitis lethargica. The president will entertain members coming from a distance to lunch at 1.30 p.m. at 8, The Rope Walk, Nottingham. Those desiring to avail themselves of this hospitality should signify their intention to Dr Rowe not later than Wednesday, July 6th.

**NORFOLK BRANCH**—The annual meeting of the Norfolk Branch will be held at the Norfolk and Norwich Hospital on Wednesday, July 6th, at 3 p.m. The president, Dr W. H. Isher will be in the chair. Agenda: Report of the Branch Council on the affairs of the Branch, and the annual financial statement, induction of the new president, Sir Hamilton Ballance, K.B.E., C.B., M.S., by the retiring president, election of a president elect and two vice-presidents, an address by Mr Ernest Miles, F.R.C.S. on rectal fistula.

**NORFOLK BRANCH WEST NORFOLK DIVISION**—The annual meeting of the West Norfolk Division will be held at the King's Lynn at the West Norfolk Hospital, on Thursday, July 7th at 3 p.m. Agenda: Election of chairman, vice-chairman, secretary, clinical secretary, members of the Executive Committee and representative on the Branch Council, annual report and balance sheet.

**NORTH OF ENGLAND BRANCH TYNESIDE DIVISION**—A golf match has been arranged to take place between the South Shields and Tyne-side Divisions on Sunday, July 3rd at Brancepeth. It will be a 18-hole match, 2 p.m. tea, 5 p.m. tournament, 6 p.m. dinner. The object of the meeting is to further social intercourse and to show that all members who have ever wielded a club will do so on the occasion, and that others who do not play will also come.

o Recklinghausen's disease treated b- injection o sodium morrhuate and ultra violet light baths the nrth a case o

auricular fibrillation and mitral disease treated by digitalis, and the last, a case of heart-block, a true Stokes Adams disease, in which rest is the only treatment.

Dr E OFENHEIM showed (1) A girl of 17 years, now looking well, who had had appendicitis with obstruction due to a tumour, which the pathologist described as a spindle celled sarcoma, three years ago (2) A woman who had a psoas abscess at 18 years of age, who wore a spinal jacket for a year, and two years later had an abscess in the thigh, 15 cm of pus was removed through the old scar, no organisms were found (3) A woman who had eczema round the nipples for two years, the skin of both breasts was now adherent and the pathologist's opinion was that this was a case of Paget's disease in the pre-cancerous stage.

Dr T H ROBERTS showed (1) A boy with tuberculous disease of the knee of three years' duration, now cured (2) A woman with a bicornuate uterus from whom he removed an ovarian cyst, the left horn contained a two months' pregnancy, a previous pregnancy had also occurred in the left horn (3) Two cases illustrating pre-operative diagnosis of ectopic pregnancy by the use of 40 per cent iodopine and x rays, believed to be the first case reported in this country. The first case showed a partly ruptured ectopic pregnancy of one and a half to two months on the left side, this was removed. The x ray showed normal patent right tube and a dilated obstructed left tube.

Mr WINSBURY WHITE showed (1) A girl, aged 4½ years, whose left kidney with two dilated ureters had been removed (2) A patient, aged 42 years, with symptoms of six months' duration, from whom a large kidney with stone in ureter had been removed (3) A man, aged 38, from whom a kidney full of stones had been removed (4) A man with fistula, but no urine came from it, right kidney removed full of stones.

Dr GUY NEELY showed a patient (whose Wassermann reaction was positive) with pulsating tumour of the groin.

#### METROPOLITAN COUNTIES BRANCH LAMBETH AND SOUTHWARK DIVISION

The annual general meeting of the Lambeth and Southwark Division was held at the British Medical Association House, Tavistock Square, W.C.1, on June 15th.

Dr G STODDART presided over a well attended meeting, at which the following officers were elected for the ensuing year, 1927-28.

Chairman, Dr R G W Saint Cedd. Vice Chairman, Dr A J McNichol. Honorary Secretary and Treasurer, Dr Michael J Fenton. Representative in Representative Body, Dr E Henrietta Jebens. Representative on Branch Council, Dr H Harvey Norton.

The retiring secretary, Dr E L M Rusby, presented the annual report of the Division, which was accepted.

The Annual Report of Council was discussed and instructions given to the representative at the Representative Meeting on many items.

A hearty vote of thanks was unanimously accorded to Dr E L M Rusby for the admirable way he had worked, and the painstaking efforts he had made on behalf of the Division during his eight years of office as honorary secretary.

#### METROPOLITAN COUNTIES BRANCH WILLESDEN DIVISION

The Willesden Division held a very instructive clinical meeting on June 21st at the Willesden Municipal Hospital, Brentfield Road, Neasden. The meeting was noteworthy for the large attendance of members. Dr G F Buchan, the medical officer of health for the Willesden District Council, had kindly arranged a demonstration at which Dr A C Troup, superintendent of the hospital, gave an interesting lecture on the control of infectious diseases, with special reference to the Schick test, the Dick test, the Schultz Chariton reaction, and the serum treatment of scarlet fever.

Dr Troup gave a full explanation of the technique of carrying out these tests. His lecture was followed by the exhibition of a number of cases demonstrating both positive and negative reactions to the Schick and Dick tests. A equivaescent case of scarlet fever was shown which, in this instance, had been greatly benefited by the administration of serum. Dr Troup pointed out that, in his experience, the Schultz Chariton blanching reaction, when negative, did not exclude scarlet fever but he found that the serum treatment of the disease was, on the whole, definitely beneficial, though at times it could not be said to come up to expectations.

After the lecture the members were hospitably entertained by the matron of the hospital to tea.

The appreciation and thanks of the meeting were tendered to the superintendent, to the matron and to Dr Buchan by the vice-chairman, Dr RICHARD GILLBARD by Dr W WOODLEY STODDART, and by Dr WILLIAM LOCK.

#### NORTH OF ENGLAND BRANCH CLEVELAND DIVISION

The annual general meeting of the Cleveland Division was held at the Zetland Hotel, Saltburn by the Sea on June 19th, when Dr R H BOTHAM was in the chair, Dr J KEVIN PENNY deputized as secretary for Dr Lowe, who was absent through illness. A letter was read from Dr G H Lowe, the secretary, resigning his resignation of that office after eleven years' service. The meeting expressed its regret that the Division was losing so capable and experienced a secretary as Dr Lowe, and recorded its appreciation of his services and sympathy with him in his illness. It was resolved to make a presentation to Dr Lowe in acknowledgement of his unstinted service to the Division, and a committee consisting of Mrs H M LEVICK, M.D., Mr W S DICKIE, Drs TOWNSEND, PENTON, and BOTHAM was appointed to receive subscriptions and to decide what form the testimonial should take.

The statement of accounts and the annual report of the Executive Committee were read and approved, and the Division placed

on record its appreciation that one of its members, Mr W S DICKIE, was chosen as president of the North of England Branch for the current year.

Votes of sympathy with Dr Burnett on the death of his wife, and with the relatives of the late Dr W SHAND, a former member of the Division, were passed. It was unanimously decided that the Division thank Mr George Watts, secretary superintendent of North Ormesby Hospital, for his courtesy during the past year. The following officers were elected for the ensuing year.

Chairman, Mrs H V LEVICK, M.D. Secretary, Dr JOHN INGLETON. Vice-Chairman, Dr R H BOTHAM.

Representatives on the Branch Council, members of Executive Committee, Ethical and Municipal Maternity and Child Welfare Committees were also elected.

#### SOUTH MIDLAND BRANCH

The annual meeting of the South Midland Branch was held at the Peacock Hotel, Northampton, immediately after the Branch Council meeting on Thursday, June 9th. Following the election of members, Dr LLOYD briefly introduced the president elect, Mr HARRIES-JONES, and vacated the chair in his favour. A hearty vote of thanks was passed to Dr Lloyd for the manner in which he carried out his duties as president for the year 1926-27.

Mr HARRIES-JONES then read a most interesting, suggestive, and helpful paper, entitled "Some points in medical ophthalmology of interest to the general practitioner." It provoked an interesting discussion in which ten members took part. Many questions were asked the president during the discussion, and some experiences in treatment were added. Dr HOPKINS of Byfield drew attention to the difficulty that he had had in sending panel patients to an ophthalmic surgeon owing to the obstructive tactics of some insurance societies, and moved the following motion, which was seconded by Dr HENDRICKSON:

This Branch is opposed to the routine that certain insurance societies have adopted of sending patients to an optician without reference to, or against the advice of the general practitioner. The Branch is of the opinion that it should be decided by the panel practitioner whether a patient should see an ophthalmic surgeon or an optician.

During the considerable discussion which ensued several members gave instances in support of the resolution, which was carried unanimously, every member present voting. Mr HARRIES-JONES replied to the discussion. At his suggestion a copy of the resolution with regard to ophthalmic surgeons in panel practice was directed to be forwarded to the Council of British Ophthalmologists.

Prior to the meeting the members were hospitably entertained to a very excellent and enjoyable lunch by the president-elect, Mr HARRIES-JONES.

#### SOUTH WALES AND MONMOUTHSHIRE BRANCH

A SOCIAL meeting of the South Wales and Monmouthshire Branch was held at the Welsh National Museum, Cathays Park, Cardiff, on June 1st. About seventy members and ladies attended. The party was received by Dr F J NORTH, keeper in geology to the museum, who explained the plans and architectural features of the building, and the general arrangement of the exhibits. Dr North conducted a party to the section of geology, and gave a most instructive address on the development of the South Wales coal fields during the last two centuries, tracing their history from the early part of the seventeenth century, and the effect of geological situation on the chief coal exporting centres. The address was illustrated by a relief map of South Wales, and a case of specimens of coal, arranged in series taken at approximately the same levels, in different areas, from Monmouthshire, passing westward to the anthracite districts of Swansea and Pembroke. The ward to the coal trade was mentioned, and the necessity for future of the coal trade was mentioned, and the necessity for developing the production of by-products of coal, from the point of view of economy, in view of the present wasteful method of burning coal in open grates. Various specimens were exhibited, and the qualities of different types explained. Several cases of fossils were examined, and Dr North gave a short demonstration.

The members and their wives were subsequently entertained to tea at Co's cafe by kind invitation of Dr R PRICHARD (Cardiff), the president. Sir LEWIS MACLEAY proposed a hearty vote of thanks to Dr North and the museum authorities for their kindness in providing such an interesting and instructive afternoon.

During tea the British Medical Association prize and certificate were presented to Mr D R L DAVIES, a student in the Welsh National School of Medicine by Dr T W THOMAS (Caeprifilly), chairman of the Cardiff Division. Mr DAVIES'S essay on gonorrhea had won the prize in competition with final year students of the Universities of Bristol and Birmingham.

#### SOUTH WESTERN BRANCH TORQUAY DIVISION

The annual meeting of the Torquay Division was held in the Torbay Hospital on May 5th. The chair was taken at the commencement by Dr H G and later by Mr E WARD of Paignton. The office bearers for the ensuing year were duly elected as follows:

Chairman, Mr E WARD. Vice Chairman, Dr R G RIDDALL. Honorary Secretary, Dr W CAMERON DAVIDSON. Representative in Representative Body, Dr JEAN MACLENNAN. Deputy Representative in Representative Body, Mr E WARD. Auditor, Dr J M JARVIS.

The annual report of the Executive Committee was read and adopted.

The HONORARY SECRETARY read the draft of a letter regarding the B.M.A. Charities Fund, which the Executive Committee recommended should be sent to every member and non-member of the Association resident in the area of the Division. A brief address

to this was suggested and it was agreed that the letter should be issued in the names of the chairman and honorary secretary of the Division.

After considerable discussion regarding the policy of the Association on the subject of the Dogs Protection Bill it was decided (by the casting vote of the chairman) that the Division should take the action recommended by the Association and the honorary secretary was accordingly instructed to write to the two members of Parliament concerned on the lines suggested.

Some discussion took place on the circular issued by the Association about contributory schemes for hospital benefit, and as to the best way to have the subject thoroughly discussed by the medical men concerned. The honorary secretary was directed to write to the medical staffs of all hospitals concerned in the area of the Division asking for their opinion of the circular, the replies to be considered by the Executive Committee before any further action was taken by the Division.

#### SOUTHERN BRANCH

The fifty-fourth annual meeting of the Southern Branch was held at Osborne House East Cowes Isle of Wight on June 15th. The Branch Council were entertained at lunch by the president elect, Major General Sir S. G. Guise-Moore KCB, after which a meeting was held. Five new members were elected. It was decided to hold meetings at Southampton in October at Portsmouth in February and at Winchester in April. The election of officers was deferred until the next meeting.

At 3 p.m. the annual meeting was held at which twenty-four members were present, when Sir S. G. Guise-Moore took the chair. The financial statement was presented and showed a credit balance of £23 15s.

The President introduced Dr. HERBERT FRENCH CBE FRCP physician to Guy's Hospital and to the Royal Household who gave an address on Venesection by the needle and bottle method and a number of other small points which was listened to by the very appreciative audience. An interesting discussion followed and many questions were asked to which Dr. French replied. A very hearty vote of thanks to Dr. French for his address was on the motion of the President carried by acclamation.

At the end of the meeting members and visitors were conducted over the State apartments by the President and later were entertained to tea by Lady Guise-Moore. Hearty thanks were accorded by all to the president and Lady Guise-Moore for their generous hospitality thus concluding one of the most enjoyable annual meetings in the history of the Branch.

#### SURREY BRANCH

The annual meeting of the Surrey Branch was held in Croydon Town Hall on June 15th with Dr. MORRIS MACLENNAN in the chair. Forty members were present.

The following officers were elected for the ensuing year:

President Mr. G. E. Newby OBE FRCS President Elect Dr. H. R. Craig Vice Presidents Dr. S. Morton MacKenzie and Dr. P. Allan Honorary Secretary and Treasurer Dr. Arnold London OBE Auditor Dr. T. T. Coraill.

Drs. A. E. Porter and H. P. Newsholme were elected to the Branch Council to represent the members holding whole-time posts in the public health service.

#### Presidential Address

At the election of the officers the chair was taken by the new president, Mr. Newby, who delivered his presidential address on research and the general practitioner. He stated that the general practitioner had many opportunities of doing research work, and he asked if the general practitioner utilized these opportunities. Many illustrations were drawn from the life and work of the late Sir James Mackenzie to show the large field which was open to the general practitioner research worker and the valuable results which might be obtained by such work. When Mackenzie started in general practice he discovered that at least 50 per cent. of his patients were suffering from something that he could not diagnose. They complained of symptoms—they had no physical signs. He set to work to investigate symptoms and the early signs of disease and he was so successful in his results in one particular line that in twenty years he was able to write a book from his own personal observation and experience which had revolutionized our ideas on heart disease. Mr. Newby urged the importance of forming local clinical research associations, either within the British Medical Association or as separate societies to do team work on some of the problems which confronted the general practitioner. The general practitioner ought to do this work because he and he only—had the opportunity of seeing patients in the early stage of disease when no physical signs were present. It symptoms were ever to obtain their proper place in research a great deal of spade work had to be done in order that their specific value might be determined. It would be no exaggeration to say that the failure of medicine to detect disease in its early stage was due to the fact that the sensations of patients had never been sufficiently investigated.

There was a large field of research awaiting exploration which could only be done by the general practitioner and that was the investigation of the incidence of disease. In different parts of the country one heard of this or that disease being more prevalent than in other places. Was that so? Did the profession know? If it was, or why was it so? Almost the only statistics available were those provided by the death certificate. The real need was for life certificates and these could only be obtained from the general practitioner. In urging that in a matter of this kind the local health authorities might assist the research

workers by supplying clerical assistance. Mr. Newby stated that the enlightened policy of the Croydon Corporation in appointing a whole-time pathologist bacteriologist and biochemist showed that the corporation was mindful of its duty to the hurgresses and it was not unlikely that it would be willing to co-operate with the local medical men in this direction. The local hospital could be made of more use to the general practitioner in two ways by post-graduate demonstrations on cases of interest and by the institution of consultation days on which general practitioners could bring difficult cases to the hospital for consultation with at least two members of the staff.

Mr. Newby concluded by asking all those interested in this matter to communicate with him and stated that if sufficiently supported he would at a later date call a meeting to consider the best means of carrying out these ideas on research by the general practitioner.

After the meeting the members visited the Croydon Corporation sewage farm and works under the guidance of Dr. OWEN FOWLER, the chairman of the Public Health Committee, who entertained the members to tea at the thorough isolation hospital where Dr. H. P. Newsholme, the medical officer of health, and the resident medical officer showed the members of the hospital.

In the evening the members dined together at the Greyhound Hotel Croydon when Mr. Newby was in the chair.

#### SURREY BRANCH GUILDFORD DIVISION

The annual meeting of the Guildford Division was held at the Royal Surrey County Hospital Guildford on June 2nd. The following officers were elected for the year:

Chairman Mr. H. B. Butler Vice-Chairman Dr. W. L. R. Fleming Honorary Secretary Dr. G. M. Bluet Representative and Deputy Representative in Representative Body Drs. A. Lyndon and T. B. Jobson.

The recommendations of Council for submission to the Annual Representative Meeting at Edinburgh were carried nem con.

#### SUSSEX BRANCH

The fourteenth annual meeting of the Sussex Branch was held at the Dolphin Hotel, Chichester on June 15th. Before the meeting a luncheon was held under the chairmanship of the president-elect, Dr. G. C. GARRATT. The health of the chairman was proposed by Dr. G. MORGAN who referred to the high esteem in which Dr. Garratt was held by his professional brethren. In reply Dr. Garratt called attention to the fact that the luncheon was provided by the Chichester and Worthing Division following the precedent established last year of not allowing the burden of the entertainment to fall upon the president.

In presenting the annual report of the Branch Council Dr. PARRY said that the six Divisions of the Branch were all in a flourishing condition. He said that the Committee on Psycho-analysis at the Annual Meeting of the Association in Nottingham last year had held several meetings and probably in the near future would present its report, which he thought would be satisfactory to the members of the Sussex Branch. The financial statement showed a satisfactory credit balance in favour of the Branch.

Dr. Garratt was formally elected president and Dr. Milbank Smith and Dr. Vernon were elected vice-presidents. Dr. Parry was re-elected for the sixth time honorary secretary of the Branch.

Dr. GARRATT referred to the great loss which the profession had sustained through the death of Dr. David Ewart who was to have filled the office of president of the Branch and to preside at that meeting.

At the termination of the meeting the members accompanied by their wives enjoyed a pleasant excursion by motor to Cowdray Park and Petworth where by the courtesy of Lord Leonfield the famous picture gallery was on view. Tea was subsequently taken at the Swan Hotel Petworth.

#### WILTSHIRE BRANCH TROWBRIDGE DIVISION

A social meeting of the Trowbridge Division was held at Lacock on June 22nd when fifteen members and eighteen guests were present. Places of interest in the village were visited. Tea was taken at the Ped Lion Hotel and afterwards the party were conducted over Lacock Abbey by Mrs. Talbot to whom a hearty vote of thanks was accorded for her kindness.

#### WORCESTERSHIRE AND HEREFORDSHIRE BRANCH

The annual meeting of the Worcestershire and Herefordshire Branch was held at Great Malvern by the kind invitation of Dr. Smyth at his house on June 16th when Mr. AINSLIE, the president, was in the chair.

The Council's report and financial statement were received. Dr. HINES (HAY) was elected president-elect for 1928-29 and Mr. BUTLER (Hereford) re-elected honorary secretary and treasurer.

It was decided to hold the autumn meeting of the Branch at Kidderminster on October 12th.

Mr. AINSLIE, prior to vacating the chair, introduced his secretary, Dr. VAIL, who thereupon succeeded to the chair as president.

Mr. T. BARTON (Worcester) showed three cases of epithelioma of the lower lip treated by Diefenbach's method and a rare case of skull injury.

Mr. AINSLIE read a long and interesting paper on inflammation of bones illustrated by numerous x-ray photographs.

A hearty vote of thanks was accorded to Mr. Ainslie for his paper and to Dr. Smyth for kindly having the meeting at his house and also for inviting the members to tea afterwards in his beautiful garden.

## NOTICES OF MOTION BY DIVISIONS FOR THE ANNUAL REPRESENTATIVE MEETING, EDINBURGH, 1927

### *Report of Royal Commission on Lunacy*

By Dr D ROXBURGH (Mylebone) That the Representative Body direct the Council to appoint a Committee for the further consideration of the Report of the Royal Commission on Lunacy, and further directs the Council to secure on the Committee an adequate number of general practitioners, on whom the responsibility of signing certificates under the Lunacy Acts mainly falls

### *Municipal Maternity Homes*

By SHEFFIELD That (with reference to Min 88 of the Annual Representative Meeting, 1926—Annual Report of Council, para 115) in the case of large towns where there is already in existence a voluntary maternity hospital the municipal maternity home should be primarily for normal cases where the home conditions are unsuitable

### *Orthopaedic Treatment*

By WINDSOR That the first recommendation contained in para 124 of the Annual Report of Council be amended to read as follows

That orthopaedic treatment whether at hospitals or clinics, should be undertaken by those who have special knowledge of the subject, and as the needs of the patient to receive the most experienced handling are paramount no restrictions should be placed on the appointment of full time officers

### *Treatment of Early Stage Mental Disease*

By WINDSOR That the recommendation contained in para 169 of the Annual Report of Council be amended to read as follows

That steps be taken to insure that in every district facilities should be provided for the specialist treatment at hospitals or clinics of patients suffering from early mental disease, that such treatment should be undertaken on a part time voluntary basis by practitioners who have special knowledge of the subject but that as the needs of the patient to receive the most experienced handling are paramount, no restrictions should be placed on the appointment of specialists who already hold full time appointments

### *Remuneration of Practitioners called in on the Advice of Midwives*

By WINCHESTER That the motion by Dartford, published on p 202 of the SUPPLEMENT of May 14th, 1927, be amended to read as follows

That the scale of fees payable by local authorities to medical practitioners called in on the advice of midwives be revised

### *Proceedings of Annual Meeting*

By FORBES and LEITH That the Council be instructed to consider the question of publishing the Proceedings of the Annual Meeting in one volume as soon as possible after the Meeting (papers and discussions being reasonably curtailed) and of making, if necessary, an extra charge for the publication

### *Illustrations in the "British Medical Journal"*

By FORBES and LEITH That the Council be instructed to consider the possibility of improving the general quality of the illustrations appearing in the JOURNAL

## National Insurance.

### LONDON PANEL COMMITTEE

At the meeting of the London Panel Committee on June 21st Dr H J CANNON presiding Dr E M J Higgins was appointed a member of the committee to represent the constituency of Camberwell in place of Dr A J Fearn resigned

### *Ophthalmic Benefit*

A letter was read from the controller of the Insurance Department of the Ministry of Health in reply to the resolution of the committee at its previous meeting in which it had requested the Ministry to receive a deputation to discuss the administration of ophthalmic benefit in relation to the action of an approved society in restricting the free choice of its members in consulting an ophthalmic surgeon. The controller drew attention to the fact that the abiding an applicant to obtain an expert medical the eyes were arrived at by discussion with the representative of the Insurance Acts Committee in conjunction with the Council of British Ophthalmologists and the Ophthalmic Benefit Committee. Any question or general application, therefore with regard to those arrangements would more appropriately in the view of the controller be discussed with those bodies than with representatives of a panel committee for one particular area accordingly he saw little advantage in arranging the meeting suggested by the committee. The secretary

of the committee was directed to draw the attention of the Insurance Acts Committee to the question raised by the action of the approved society in question in restricting the free choice of its members in consulting an ophthalmic surgeon, and the name of the approved society was also sent, at his request to the controller, together with a copy of the notice to which exception was taken by the committee, in order that the Insurance Department of the Ministry might consider whether any action should be taken with the society.

The committee also had before it a complaint from a practitioner that a certain approved society had refused to accept a certificate on a printed form issued by the committee for the use of practitioners in recommending their insured patients to consult an ophthalmic surgeon. The secretary of the society in question had stated that instructions had been issued by the Ministry of Health to refuse such certificates. The Ministry had been communicated with as to the correctness of this statement, and from the reply of the Ministry it would appear that while no instructions had been issued to approved societies that they should refuse to accept such certificates, the Ministry apparently agreed with the society that these ophthalmic certificates were being issued indiscriminately by practitioners to their insured patients. After discussion, the committee agreed to a resolution stating that the communication from the Ministry on this subject was in its factory, and placing on record its disagreement with the Ministry that certificates recommending insured patients to consult an ophthalmic surgeon had been, or were being, issued indiscriminately by practitioners in London.

### *Surrender of Forms of Medical Record*

It has been proposed that the Panel Committee should co-operate with the Insurance Committee in communicating with practitioners who failed to return forms of medical record as required under the regulations. The chairman of the Medical Service Subcommittee, however, expressed the view that the Insurance Committee could not supply the Panel Committee with the names of offending practitioners because, the information being privileged such action would constitute a breach of confidence. The Panel Committee thereupon consulted its solicitors whose opinion was that the subcommittee was bound to investigate any particular case of failure to return the forms that in such investigation it must take reasonable steps to ascertain the facts, and that the co-operation of the Panel Committee in that connection would not involve a breach of confidence or expose the Insurance Committee to any action by a practitioner. It was agreed to forward a copy of this opinion to the Insurance Committee.

### LONDON INSURANCE COMMITTEE

It was reported to the London Insurance Committee, on June 23rd, that the Ministry had reviewed the case of a practitioner whom the committee had already decided to censure severely for breach of the terms of service with regard to attendance on an insured person and the treatment provided and after taking into consideration representations by the practitioner, had decided to withhold the sum of £50 from the money payable with respect to medical benefit with a view to this sum being recovered from the practitioner by deduction from his remuneration. In two cases in which chemists were found to have committed a breach of the terms of service by inaccurate dispensing of prescriptions, the sums of £2 in the one case and of £1 in the other were withheld by the Minister.

The number of prescriptions dispensed personally for their insured patients by practitioners in London during the first quarter of 1927 was 314 the cost being £44 18s. During the same quarter 442 prescriptions for serums and vaccines and 234 prescriptions for insulin were dispensed by chemists for insured persons.

The Insurance Committee and the Panel Committee are at variance over an application by a practitioner with 157 insured persons on her list, for permission to employ an assistant in her insurance practice. The practitioner desires an assistant in order that she may be released from her morning surgery in time to attend to her duties in the afternoon as school medical officer the schools being at some distance. The Panel Committee is of opinion that permission might be given but the Insurance Committee holds that as the terms of service require the practitioner to provide personal service for her insured patients except in certain defined circumstances she should not undertake additional and extraneous duties which prevent the proper fulfilment of the contract, and that permission must be withheld.

## Correspondence.

### *Medical Missionary Breakfast at the Annual Meeting*

SIR—On behalf of the Medical Prayer Union, the Medical Missionary Breakfast held in connexion with the Annual Meeting of the British Medical Association will this year be arranged for under the auspices of the Edinburgh Medical Missionary Society. The date allotted by the British Medical Association Council is Friday, July 22nd, and the hour 8.30 a.m.

May I through your columns draw attention to this engagement, and ask all who may desire to be present to be good enough to let me have a postcard at their early convenience, with their names and addresses, so that invitation cards may be sent to them in due time? A card of invitation is issued to all who are interested in the medical missionary

ROCHFORD L 104—District Medical Officer and Public Vaccinator for the Southend on Sea (1st) District. Salary £120 per annum and usual

H H SCOTT (London), Professor L P LELAND (London), Mr  
J W BRITILLANK, PRCVS (London), Mr ALFRED GORFON  
(Edinburgh), Mr T W M CAMERON (London), and Mr JAMIE  
McALLAN (Aberdeen).

## THERAPEUTICS AND PHARMACOLOGY

President Professor J A GUNN, MD, DSc (Oxford),  
Vice Presidents Professor A J CLARK, MC, MD, FRCP  
(Edinburgh), Professor FRANCIS R FRISLER, MD, FRCP  
(London), D P POULTON, MD, FRCP (London), Mr W H ANDREWS  
(London), L G HOLMES, MB, BChir, Pharmacology,  
Honorary Secretaries L G HOLMES, MB, BChir, Pharmacology,  
logical Laboratory, Cambridge, C G LAMMIE, MC, MB,  
FRCP Ed, 31, Dimsheugh Gardens, Edinburgh.

The following provisional programme has been arranged  
Wednesday, July 20th - 10 a.m. to 12 noon Discussion: Clinical  
Methods of Administration and Therapeutic Uses of Oxygen.  
To be opened by Dr E P POULTON (London), followed by Dr  
H WHITBREAD DAVIS (Leeds) and Dr W T RICHIE (Edinburgh).  
12 noon to 1 p.m. Paper: Professor J A GUNN (Oxford),  
Expectorants.  
Thursday, July 21st - Discussion: The Therapeutic Uses of  
Calcium Salts. To be opened by Professor F R FRISLER (London),  
followed by Dr L G PARSONS (Birmingham), Mr C P STEWART  
(Edinburgh), Biochemical Aspect, Dr G H PEACOCK (Edinburgh),  
Pharmacological and Therapeutic Aspect, Professor L BURN  
(Strasbourg), Dr G C LINDLER (London), Totony, and Dr  
N F C BURGESS (London).  
Friday, July 22nd - Discussion: The Action and Uses of Ovarian  
Extracts. To be opened by Professor W L DIXON (Cambridge),  
followed by Dr KATHLEEN A COWARD (London), Standardiza-  
tion, Mr A S PARKES (London), Physiological, Dr W L  
ADDIS (Manchester), Clinical, and Professor J M MURRO KILL  
(Glasgow), Gynaecological.

## DISEASES OF CHILDREN

President Professor JOHN FRISLER, MC, MD, ChM,  
FRCS Ed (Edinburgh).  
Vice Presidents H CHARLES CAMERON, MD, FRCP (London),  
ALEXANDER DINGWALL FORDYCE, MD, FRCP Ed (Edinburgh),  
CHARLES MCNEIL, MD, FRCP Ed (Edinburgh), Miss HELEN M M MACKAY MD,  
Honorary Secretaries Miss HELEN M M MACKAY MD,  
28, John Street, Bedford Row, London, W.C.1, LEWIS THATCHER,  
MD, FRCP Ed, 8, Melville Crescent, Edinburgh.

The following provisional programme has been arranged  
Wednesday, July 20th - Discussion: Acute Pneumonia in Early  
Childhood. To be opened by Dr CHARLES MCNEIL (Edinburgh),  
and Dr AGNES R MACGREGOR (Edinburgh), Dr J HUGH THUR-  
FIELD (London), Colonel W A ALEXANDER (Edinburgh),  
NORMAN S CARVICHALL (Edinburgh), Mr F C PYBUS (Newcastle),  
Acute Pulmonary Conditions in Childhood, illustrated by spec-  
imens, x ray prints, large sections and microscopic preparations.  
Surgical Demonstration at Royal Edinburgh Hospital for Sick  
Children.  
Thursday, July 21st - Discussion: Acute Intestinal Obstruction  
in Infancy and Childhood. To be opened by Mr ALLY McLENNAN  
(Glasgow), followed by Mr L E BURNINGHAM (Edinburgh),  
Miss G M A HERZELD (Edinburgh), Mr F C PYBUS (Newcastle),  
on Tyne, and Mr NORMAN M DOIR (Edinburgh).

**COMPARATIVE MEDICINE**

**President** Principal O CHARNOCK BRADLEY, M.D., D.Sc., F.R.C.V.S. (Edinburgh)  
**Vice Presidents** Professor J.B. BURTON, M.A., F.R.C.V.S. (Cambridge), T.A.E. GRAY, M.D., D.Sc. (Edinburgh), Major G.W. DUNNIN, M.R.C.V.S. (London)  
**Honorary Secretaries** T.W.M. CAMERON, Ph.D., D.Sc., M.R.C.V.S., London School of Hygiene and Tropical Medicine, 23, Endsleigh Gardens, London, W.C.1, J. RUSSELL GILG, M.P.C.V.S., Royal (Dick) Veterinary College, Edinburgh.

The following provisional programme has been arranged

**Thursday, July 21st**—(Joint meeting with Section of Pathology and Bacteriology) Discussion Immunity To be opened by Dr R.A. O'BRIEN (Beckenham) and Professor CARL H. BROWNE (Glasgow), followed by Professor R. MUIR (Glasgow), Dr HEDLEY D. WRIGHT (London), Colonel W.F. HARVEY (Edinburgh), and Professor T.J. MACKIL (Edinburgh)  
**Friday, July 22nd**—(Joint meeting with Section of Pathology and Bacteriology) Discussion Aspects and Problems of Comparative Medicine To be opened by Professor BASIL BURTON (Cambridge), followed by Major G.W. DUNNIN (Edinburgh), Dr ANDREW BARRON (London), Dr W.H. ANDERSON (Edinburgh), Dr H.H. SCOTT (Agriculture), Dr F.A.E. GRAY (Edinburgh), Dr J.W. BRITTELBANK (London), Professor FRIPER (Edinburgh), Mr T.W.M. CAMPION (London), Mr ARTHUR GORTON (Aberdeen), and Mr JAMES MCALLAN (Aberdeen)

**The following Sections will meet on One Day**

**DERMATOLOGY**

**President** ROBERT CRANSON LOW, M.D., F.R.C.P. Ed (Edinburgh)  
**Vice Presidents** W. HIRBLERT BROWN, M.D. (Glasgow), H.D. HALLIDAY, M.D., F.R.C.S. (London)  
**Honorary Secretaries** ROBERT AITKEN, M.D., F.R.C.P. Ed, 8 Palmerston Place, Edinburgh, F.D. HOWITT, M.D., 87, Harley Street, London, W.1

The following provisional programme has been arranged

**Thursday July 21st**—Discussion The Uses and Limitations of Ultra violet Radiations in Dermatology To be opened by Dr S.E. DORE (London)  
**Papers** Dr H.C.G. SEMON (London), The Value of Kravolgan in Lupus Erythematosus, Dr G.B. DOWLING (London), The Treatment of Tinea Capitis with Thallium Acetate

**TROPICAL DISEASES**

**President** ANDREW BALFOUR, C.B., C.M.G., M.D., F.R.C.P. Ed, D.P.H. (London)  
**Vice Presidents** Lieut Colonel E.D.W. GRIGG, M.D., D.Sc., F.R.C.P. Ed (Edinburgh), Lieut Colonel W.F. HARVEY, C.B., M.D., C.M. D.P.H., F.R.C.P. Ed (Edinburgh), Lieut Colonel W.P. MACARTHUR, D.S.O., O.B.L., M.D., F.R.C.P. Ed, D.P.H. (London)  
**Honorary Secretaries** A.R.D. ADAMS, M.B., Ch.B., D.T.M., School of Tropical Medicine, University of Liverpool, J.F.C. HAYMAN, M.C., M.B., F.R.C.P. Ed, D.P.H., Bureau of Hygiene and Tropical Diseases, 23 Endsleigh Gardens, London, W.C.1

The following provisional programme has been arranged

**Wednesday, July 20th**—10 to 11 a.m. Discussions (1) Amoebic Dysentery To be opened by Professor WARRINGTON YORKE (Liverpool), followed by Dr P.H. MAYSON BARR (London) (Treat ment and Epidemic Illustrations of Sigmoidoscopy Appeal ances) Dr J. GORDON THOMSON (London), and Dr N. SWILLLEN GRUBER (Amsterdam)  
 11 a.m. to 1 p.m. (2) Some Problems of Malaria Prophylaxis To be opened by Lieut Colonel S.P. JAMES (Ministry of Health), followed by Sir WILLIAM T. PROUT, C.M.G., O.B.L. (London), Lieut Colonel I.D.W. GRIGG (Edinburgh), Dr L.W. PICKERILL (Rome) and Dr N. SWILLLEN GRUBER (Amsterdam)  
**Afternoon** Venereal Demonstration Professor W. YORKE and Dr A.I.D. ADAMS Amoebic Dysentery There will also be a demonstration of maternal font by Professor W.S. PATTON (Liverpool)

**FORENSIC MEDICINE**

**President** Professor H. HARVEY LITTLEJOHN, M.B., F.R.C.S. Ed (Edinburgh)  
**Vice Presidents** The Right Hon. Earl RUSSELL (London), Sir WILLIAM SCHRODLI, K.B.E. (London), Professor SIDNEY A. SMITH, M.D., D.P.H. (Caro)  
**Honorary Secretaries** D.J.A. KIRK, M.B., Ch.B., D.P.H., M.R.C.P. Ed, Forensic Medicine Department, University, Teviot Place, Edinburgh, Professor J.E.W. MCALLAN, M.D., D.P.H., 65 Green Lane, Stonecroft, Liverpool

The following provisional programme has been arranged

**Thursday July 21st**—Discussions (1) Alcohol and the Motorist Relations To be opened by Dr G. CARTER (Sheffield) followed by Dr E.H. NICHOLSON (London) in connexion with the Section of the museum of the Professor M.J. Wade for a demonstration of the (Criminal) forensic medico-legal interest

**12 noon** Criminal medico-legal interest

**Tissues in vitro, b**

**Street**

**TUBERCULOSIS**

**President** S. VERA PEARSON, M.D. (Mundesley)  
**Vice Presidents** WILLIAM BRAND, M.B., C.M. (London), I. DR W. SNOWDEN, M.D., C.B.E. (Ringwood, Hants), LINESI WAT, M.D., D.Sc., M.R.C.P. Ed (Edinburgh)  
**Honorary Secretaries** J.C. SIMPSON, M.C., M.B., Ch.B., D.P.H., Southfield Sanatorium Colony, Liberton, Edinburgh, R.L. LIND, M.C., M.D., King Edward VII Sanatorium, Midhurst

The following provisional programme has been arranged

**Friday, July 22nd**—10 a.m. Discussions (1) Radiology and Diagnosis of Intrathoracic Tuberculosis from the Point of View of Specialist and Practitioner To be opened by Mr H. MORRISON (Vale of Clwyd Sanatorium, North Wales), followed by Dr DAVIES (Vale of Clwyd Sanatorium, Manchester), and Dr J.M. RIST (Paris) Dr J. LOGAN STRAUAT (Manchester), and Dr J.M. WOODBURN MORISON (Edinburgh) (2) Pathology of the Tuberculosis of Childhood and its Bearing on Clinical Work To be opened by Professor EUGENE L. ORIE (Washington University), followed by Dr R.G. CANN (London) and Dr P.F. ARMA (London) (3) Interrelation of Physician and Surgeon in Regard to Non-pulmonary Tuberculosis To be opened by Dr D.A. POWELL (Cardiff) and Professor JOHN TRISLER (Edinburgh), followed by Mr G.H. GILLIS (Oxford)

**2.30 p.m. Demonstrations, x-rays, etc**

**VENEREAL DISEASES**

**President** DAVID LELS, D.S.O., M.B., F.R.C.S. Ed (Edinburgh)  
**Vice Presidents** ARCHIBALD CAMPBELL, M.B., Ch.B. (London), R. SPOTTS, M.B., Ch.B. (London), F.C. DOBLE, M.R.C.S., L.R.C.P., 93A Harley Street, London, W.1, Miss MARY FORBES LISTON, M.B., Ch.B., 33, Cornhill Bank, Edinburgh

The following provisional programme has been arranged

**Friday, July 22nd**—Morning session Discussion The Value of Routine Examination of the Cervical Fluid with regard to (a) More Accurate Knowledge, (b) Prognosis, (c) Treatment To be opened by Mr C.H. MILLS (London), followed by Prof. or G. G. M. ROBERTSON, F.R.C.P. Ed (Edinburgh), Colonel L.W. HARRISON (London), Dr GEORGE RIDDIOCH (London), Dr J.G. GILLIS (Edinburgh), and Dr D.A. HENDERSON (Glasgow)

Clinical cases illustrating Types of Neuro-syphilis will also be shown

**Afternoon session, 3 p.m.** Discussions (1) The Employment of "Polar Body" Developing strains of the Gonococcus in the Treatment of Gonococcal Infection To be opened by Major L.C. LAMBART, D.S.O., R.A.M.C. followed by Colonel L.W. HARRISON (London) and Dr DAVID WARSON (Glasgow) (2) The Place of Bismuth in the Treatment of Syphilis To be opened by Dr L.T. BURL, D.S.O. (Edinburgh), followed by Dr L.T. BURL, D.S.O. (Manchester) Dr J.C. BUCKLEY (Nottingham) Dr W.L. SNODGRASS (Glasgow), and Dr MURRAY MACNICOL (Edinburgh)

**RADIOLOGY**

**President** J.M. WOODBURN MORISON, M.D., C.M. D.M.R.E. (Edinburgh)  
**Vice Presidents** M.R.J. HAYES, F.R.C.S.I. (Dublin), I. MORRIS, M.D., B.Sc., D.M.R. and E. (Liverpool)  
**Honorary Secretaries** W. CRICHTON FORBES, M.B., Ch.B., D.M.R.E., 5, Hermitage Drive, Edinburgh, JOHN MUIR O'BRYEN, M.B., Ch.B., British Institute of Radiology, 32, Welbeck Street, London, W.1

The following provisional programme has been arranged

**Wednesday, July 20th**—Discussions (1) 10 a.m. X-rays in the Diagnosis of Intrathoracic Growth To be opened by Dr STANLEY MELVILLE (London) followed by Mr C. THURSTON (Liverpool), Dr A. FLETCHER (Edinburgh), Dr HOLLAND (Liverpool), Dr A. FLETCHER (Glasgow) (2) 11.30 a.m. X-rays and Radium in the Treatment of Carcinoma of the Breast To be opened by Dr N.S. IZZAT (London) followed by Dr J.H.D. WEBSTER (London), Dr A.D. BUCKLEY (Manchester), and Dr M.R.J. HAYES (Dublin)

**HISTORY OF MEDICINE**

**President** JOHN D. COHEN, B.Sc., M.D., F.R.C.P. Ed (Edinburgh)  
**Vice Presidents** ALFRED CHURCH, M.D., F.R.C.P. (London), R.W. LIND, M.D., D.Litt., F.R.C.P. (London), Beckenham  
**Honorary Secretaries** WALTER J. DILLING, M.B., Ch.B., D.P.H., M.R.C.P. Ed, 11, Avenue Avenue, Liverpool, ADAM CAMPBELL, M.B., Ch.B. Ed, Pharmacological Department, University of Edinburgh

The following provisional programme has been arranged

**Friday July 22nd**—10 a.m. Discussion The Historic Evolution of Disease To be opened by Sir ALFRED CHURCH (London) followed by Dr G. MUIRSON (Edinburgh) (1) Cause and Effect of Epidemics and their Relationship to the Community Conditions, and Miss M.C. BURL (Edinburgh) (2) The Influence of Industrialism upon the Health of the Community To be opened by Professor A.J. CLARK (Edinburgh) The Historical Aspect of Quackery 12.30 p.m. Professor A.J. DILLING (Liverpool), The Methods of Introduction of Drugs of Old Physicians (1) Dr ALFRED CHURCH (London) (2) The Practice of Surgery in the Early 17th Century, as illustrated in the Writings of Master Peter Lowe

K G, O M, will preside, and that short addresses will be delivered by Sir William Watson Cheyne, Professor Tuffier (Paris), Professor Harvey Cushing (Harvard University), and Professor John Stewart (Halifax, Nova Scotia).

Throughout the week of the Association Meeting a museum of Lister relics will be on view in the Upper Library of the Old University. The relics will be gathered from many sources. The unique interest of the exhibits will be due largely to the co-operation and liberality of the directors of the Wellcome Historical Medical Museum, London.

A *Lister Memorial Volume* has been prepared and will constitute the book of the Edinburgh Meeting of the Association. A copy will be presented to each member of the Association on registration in the reception room. The volume, edited by Dr Logan Turner, will contain sketches and reminiscences by former house-surgeons of Lord Lister, two of his own scientific addresses, and a series of letters. A section of particular interest is included dealing with the lives of Lister's fellow residents in the Edinburgh Royal Infirmary during the summer of 1854. Sir Edward Sharpey-Schaefer contributes a sketch on Lister's work as a physiologist. Mr Miles writes on "Surgery prior to Lister's time," and Professor John Fraser on "The influence of Lister's work on surgery."

Memorial inscriptions have been placed on the walls of the houses which Lister occupied successively in Edinburgh—namely, 11, Rutland Street, and 9, Charlotte Square.

A prize of £25 and a gold medal are to be awarded to the writer of the best essay on "The influence of Lister on surgery." The prize is open to students and graduates of not more than one year's standing in any medical school in the British Empire. The name of the successful essayist will be announced at the public meeting.

#### ANNUAL DINNER

As already intimated, the Annual Dinner of the Association will be held in the Music Hall, George Street, on Thursday, July 21st. The hour of the dinner will be 7.15 p.m. prompt. It is desirable that early application be made for tickets, the price of which has been fixed at 15s., exclusive of wine. Such applications should be made to the local general secretary, Dr Feigus Hewat, 14, Chester Street.

Dinner tickets will be available for members of the Association up to 4 p.m. on Wednesday, July 20th, and will be obtainable at the reception room on presentation of the member's card. A plan of the tables will be on view at the reception room.

If seats are available, members may obtain tickets for ladies or other guests, after 4 p.m. on Wednesday, July 20th.

#### REDUCED RAILWAY FARES TO EDINBURGH

The usual concession to members of the British Medical Association in regard to railway fares will apply to the Annual Meeting in Edinburgh this summer. The railway companies in Great Britain (except the Metropolitan, Metropolitan District, and London Electric Railway Companies) have agreed to issue passenger tickets to Edinburgh, available from July 13th to 25th, at the ordinary single fare and one-third for the double journey, with a minimum adult fare of 1s. A printed voucher filled in by the applicant and signed by the Financial Secretary of the Association, must be given up at the booking office when the ticket is bought. These vouchers will be obtainable in due course from the Finance Department, British Medical Association, Tavistock Square, W.C.1. The cheap fare concession will, in addition to applying from stations in Great Britain, also operate from the Irish ports by railway-owned steamers, and by the boats of the Belfast Steamship, British and Irish Steam Packet, and the City of Cork Steam Packet Companies, and of Messrs Burns and Laird, Ltd.

#### HOTEL ACCOMMODATION

The Hotels and Lodgings Committee has practically completed its arrangements for coping with the large numbers who are expected to visit Edinburgh in July. In order to secure the accommodation which is believed to be

necessary, the Committee has definitely engaged all the available rooms in the city, and will allocate these to applicants in rotation. The Scottish Medical Society (Dr Dwyer) has undertaken to do this work for the Committee, and applications for rooms should be sent to him at 6, Drumsheugh Gardens. A form for the purpose has been prepared for the convenience of members; it was printed in the advertisement pages on June 4th (p. 18). The accommodation is grouped in three classes—namely:

1 Hotels, whose tariff for bed and breakfast ranges between 8s. 6d. and 14s. The number who can be accommodated in these is comparatively limited.

2 Private hotels and boarding houses, at prices from 5s. 6d. to 8s. 6d. for bed and breakfast. Of these there is a large number, all of them comfortable.

3 Hostels where the tariff is 8s. for bed and breakfast. Not many of these are available, but those that are can be recommended.

It will facilitate other arrangements if members who intend to be present at the Annual Meeting will notify their intention whether they have already secured rooms or not. Early application for rooms is earnestly desired.

#### GOLF COMPETITIONS

##### *The Ulster and Childs Cups*

The Ulster and Childs Cups will be played for on Thursday, July 21st, at Muirfield, commencing at 9.30 a.m.

Both cups will be played for during the same round. The Ulster Cup is open to all members of the Association, the maximum handicap allowed being 18, the Childs Cup is open to all members of the Association who have a handicap of 10 or over, 18 again being the maximum allowed. Play in both cases is against bogey. If the Ulster Cup is won by any competitor with a handicap of 10 or over the Childs Cup will be presented to the player (with a handicap of 10 or over) with the next lowest score.

Conditions of play are as follows:

1 One round of eighteen holes to be played on Thursday, July 21st, at Muirfield. In the event of a tie the last nine holes to decide.

2 Competitors are not permitted to put in previous play on the course on the day of the competition.

3 Intending competitors are required to furnish with their entry a certificate signed by their club secretary stating (a) their lowest handicap, (b) the bogey score of their own course, and (c) the length of their course.

4 Entries to be made at the Reception Room, Waverley Park & Hall, before 6 p.m. on Wednesday, July 20th.

5 Competitors may choose their own partners, although partners will be arranged for by the committee on notice being given at the time of entry.

6 Play to commence at 9.30 a.m., no cards to be issued after 3.30 p.m.

##### *Treasurer's Cup Competition*

The final stage of this competition will be played on Friday, July 22nd, at Gullane No. 1, commencing at 2 p.m. The handicap allowed for the final stage will be the lowest handicap of the competitor as at July 22nd. Competitors may choose their own partners. In the event of a tie the last nine holes to decide.

##### *Notts Ladies' Challenge Cup Competition*

This competition will be held on the morning of July 20th at Gullane. The rules governing it are as follows:

The competition to be played under the Ladies' Golf Union Handicap Rules (metal round eighteen holes) during the Annual Meeting. The winner to hold the cup for twelve months. In the event of a tie the last nine holes to decide. Entrance fee 2s., to be paid to the secretary of the Local Ladies' Sports Committee.

The competition will be open to the following: Lady members, wives of members, and daughters of members. Other relatives accompanying members to the meeting may be allowed to compete at the discretion of the Local Ladies' Sports Committee.

Each competitor to give their full name, address, and J.G.U. No. to the secretary of the competition, and to pay the entrance fee to the secretary, of the Ladies' Sports Committee, Mrs. Mercer, 3, Rothesay Place, Edinburgh.

#### GARAGE ACCOMMODATION

Garage accommodation for at least 1,125 cars will be provided; applications should be made to Dr J. R. Dwyer, 6, Drumsheugh Gardens, Edinburgh.

praise will be made at Scott's View on Bemeiside Hill. The road next turns round Bemeiside House, presented by the nation to Earl Haig as a tribute to his services during the war. A halt will be made at Dryburgh Abbey, the seat of the monastic cell of St. Modan from the sixth century, and the burial place of Sir Walter Scott. Crossing the Tweed at St. Boswells, the route now follows the south bank of the river, past the ruins of the old border fortress of Roxburgh. Floors Castle lies on the left—we will hope glistening in the sunshine. Passing through Kelso, the way leads to the north and back to Floors Castle, where the party will be entertained at tea by His Grace the Duke of Roxburgh. The road back to Edinburgh passes over Southa. From the top a view over a wide expanse is obtained. The Lothians lie at our feet. Just across the Firth is the "Kingdom of Fife," with Stirling further to the west. Beyond lie the Ochil Hills, and in the distance are the peaks of the Grampian Mountains. The road we travel has been tried by the feet of many generations. It gave passage to Scottish hosts on their way south and to invading English armies. Descending towards Edinburgh, we pass Southa Aisle, an ancient hospitium, Crichton Castle, and after passing through Dalkeith with its palace we see the ruins of Mary Queen of Scots's residence at Craigmillar Castle. The town above so shortly described embraces over 120 of the best miles in Scotland. It is full of associations with Scott, Stevenson, Andrew Lang, and Crockett, and tradition and story of the Roman occupation, of the perpetual wars along the Border, of the Covenanters, and of monastic life in the abbeys along the Tweed will be constantly recalled by the various features of the beautiful and romantic scenery amid which the excursionists will travel.

#### EXCURSION TO FIFE AND ST ANDREWS.

On Saturday, July 23rd, a party limited to 100 will leave the Waverley Station by special train at 9.22 a.m. and proceed by way of the Forth Bridge, passing the Hawes Inn mentioned in *The Antiquary* and Stevenson's *Kidnapped*. The naval base of Rosyth will be seen on the left. After emerging from a tunnel, St. Margaret's Hope—where "St. Margaret" landed in Scotland—will come into view. Leaving behind Kirkcaldy, with its associations with Adam Smith, the party will arrive at Ladybank, be met by chaperones, and proceed to Falkland Palace. This building has associations with Scottish history from the days of King Robert the Bruce to Charles II, and was the scene of the alleged murder of the young Duke of Perth by his uncle Albany (see *The Fair Maid of Perth*). Here James the Fifth died and Mary was a frequent visitor, fleeing from the exhortations of John Knox. The party will leave Falkland Palace at 11.30 and, by the kind invitation of Mr. and Mrs. Leslie Melville, will visit Melville House, which was built by the first Earl of Melville in 1692. Here are pictures of Mary Queen of Scots, Clara House, Gustavus Adolphus, and an interesting exhibition of letters by most of the Stewart kings. The party will next proceed by the old Royal Road which was followed by the kings of Scotland in passing to and from St. Andrew. Half-way lies Cupar, the county town. Here are the ruins of the castle in which Macbeth murdered Duncan, and from which Wallace drove the English, and here Sir David Lindsay's plays were acted. At Pittscottie the route follows the track of the murderers of Archbishop Shrap over Angus Mun, where he was killed. At St. Andrews lunch will be provided by the courtesy of the Free Burgh. The Cathedral, Castle, and University Buildings will then be visited, after which tea will be provided at the Sir James Mackenzie Chemical Institute by the courtesy of Dr. Martland Ramsay (the Director) and Mrs. Martland Ramsay. The special train will leave St. Andrews at 5.10 p.m., arriving at the Waverley Station, Edinburgh, at 7 p.m. Price of ticket inclusive of rail, motor, and entrance fees, 12s. 6d.

#### IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

The annual lunch of the above Association will be held at 1 o'clock sharp, on Wednesday, July 20th, at Messrs. Ferguson and Forsters, 129, Princes Street, Edinburgh. Tickets, 4s. each (exclusive of wines), may be obtained from

the honorary secretary of the Province, Dr. Falkland L. Carr, 67, King's Road, Harrogate. Members of the Association are asked to bear in mind that Wednesday, July 20th, is the date allotted to the Easter Centenary celebrations, and there will be many appointments in the afternoon, so that punctual attendance at the luncheon is essential.

### Meetings of Branches and Divisions

Where the wife and herfordshire branch Hereford Divis on  
-A meeting of the Hereford Division will be held at 20 East  
St. Hereford on Monday July 11th at 5.15 p.m. Members  
are asked to bring the Settlements of April 23rd and 30th and  
June 20th Agenda Report of social meeting unemployment po  
-graduate leavers in institutions to representative committee.

L. FERRIS SCOTT, Secretary

A discussion on this problem in general practice was opened by Dr. E. A. B. who also made the following remarks on the letters which had appeared recently in the British Medical Journal referred to the need of care in the use of a particular drug to the formation of habit to the detriment of the frequent use of chloroform.

etc., and to the opinions of specialists regarding drug addicts and the value of suggestion exercise, and careful diet. In the subsequent debate DIS HUGGINS, BAILEY, TURNER, ROSE, ASHBY, COVENTON, KEVISH, L W REYNOLDS, and the CHAIRMAN took part. It was evident that the discussion was a very useful one to the general practitioner, and the CHAIRMAN voiced the feeling of the meeting by proposing a hearty vote of thanks to Dr Brasher, which was carried unanimously with acclamation. Tea was served during the discussion.

#### STAFFORDSHIRE BRANCH

The annual general meeting of the Staffordshire Branch was held at the Stork Hotel, Walsall, on June 23rd. The retiring president, Dr W C ALLARDICE, introduced the president-elect, Dr J A M CLARK, who thereupon took the chair. The report and financial statement of the Branch was read and approved. Dr G H SOWRY (Newcastle) was elected president-elect, and Dr Adam WHITE (Newcastle) and Mr Reginald ALEOCK (Hanley) were re-elected honorary secretary and treasurer respectively. The president, Dr J A M CLARK, read a paper on co-ordination and unification in the public health service.

#### SUFFOLK BRANCH

The annual meeting of the Suffolk Branch was held at the Fehr Hotel, Felixstowe, on July 2nd. There were over forty members present. Dr H H BROWN, OBE (Ipswich), was elected president, Dr Mullock (Southwold) president-elect, and Dr Giuseppe was re-elected honorary secretary and treasurer.

Dr BROWN gave his presidential address on infection and trauma and intravenous therapy. Mr R STANLEY LEWIS, MI Meech E, gave an address on the philosophy of useless.

Seventy members and their wives were entertained to lunch by Dr and Mrs Brown at the Fehr Hotel, and over eighty members and their wives were entertained to tea at Trevoe by Dr and Mrs Giuseppe.

#### WEST SOMERSET BRANCH

The annual meeting of the West Somerset Branch was held at Chard on June 24th when the new president, Dr E N JUPP, took the chair. Dr F J GOMEZ was elected honorary secretary and treasurer. The Branch Council was appointed to act also as the Ethical Committee of the Branch. Various questions of local interest, and also the Supplementary Report of Council, were considered. Some discussion took place regarding the new proposal for dealing with insured ophthalmic cases, and the meeting instructed Dr Macdonald to oppose at the Representative Meeting the recommendation of Council with regard to provision of ophthalmic benefit through clinics. Before the meeting the members had lunch at the George Hotel, Chard, and after the meeting they were entertained to tea by Dr and Mrs Jupp at their residence. A tennis party and excursions had been arranged, but owing to the inclemency of the weather these had to be abandoned.

## National Insurance.

### PERIODICAL MEDICAL EXAMINATIONS

#### DEPUTATION TO THE MINISTER OF HEALTH

THE RIGHT HON. NEVILLE CHAMBERLAIN, M.P., Minister of Health, received, on June 28th, a deputation from the People's League of Health (introduced by Viscount Burnham), which submitted the following resolutions:

1. In the opinion of this meeting the establishment of periodical medical and dental examinations of all persons insured under the national insurance laws is urgently called for, as an economic proposition having regard to the return so to be obtained in health and productive efficiency. Every such insured person, when accepted as a patient on a doctor's panel, shall be by that doctor medically examined and the result of that examination placed on record. Preliminary examination should apply also to dental examination when that additional benefit is included and available under the national insurance laws.

2. In view of the fact that there are over 1,643,700 unemployed persons excluding minors at the present time in our country, this meeting is of the opinion that the People's League of Health should urge the Government as it did in May, 1922, to consider: (a) the effect of unemployment and the dole (unemployment insurance benefit) on the health and habit of the nation, both from the psychological and physiological aspects; (b) the necessity for the adoption of an alternative system by the Government in dealing with unemployment, by which the millions now being spent in unemployment insurance benefit shall be directed into a channel of productivity; (c) The establishment of an Unemployment Committee composed of the best brains of the country including medical and other scientists, to deal with unemployment, its cause, treatment, and prevention.

3. That the People's League of Health endorses the Government's action in regard to the new regulations governing food preservatives as set out in Statutory Rules and Orders, 1925, No 775, paragraph 69755, dated August 4th, 1925. That the League's campaign for safeguarding the people's food from adulteration and impurities has helped in no small way to bring about this victory. That in order to meet these new regulations and to prevent the waste and possible shortage of perishable foods during the hot months of the year, this meeting is of opinion that the

proper means of transport for such food and the establishment of adequate cold storage in this country should occupy the immediate attention of railway companies and local authorities.

4. That the above resolutions shall be placed before the Government at the earliest possible moment.

Various speakers addressed the Minister on the advisability, from the point of view of improvement of the people's health, of compulsory examination upon entering national insurance, with repetition at such intervals as might be deemed desirable so that an accurate record might be kept. By this means the earliest symptoms of disease could be detected, and people could be advised as to change of occupation or proper treatment. Every opportunity should be taken of such periodical examinations to educate the people and to give them hints regarding their health.

Professor P S LEEHAN spoke of the enormous saving of life and money consequent on the earliest possible detection of incipient disease. As the result of examination, it had been found that 80 per cent of the children in Glasgow were in need of dental treatment. Of 4,500 children examined in Glasgow only 12 were found to have sound teeth. Even in the better class university population in America there were 91 per cent requiring dental treatment. In cancer, by early consultation and treatment, the number of cases requiring immediate attention had been reduced by 50 per cent, and the proportion of malignant tumours by a similar amount. In Framingham (Massachusetts) periodical examination had been carried on in an industrial centre, with the result that they had reduced the prevalence of tuberculosis by 55 per cent in ten years.

Dr WILLIAM HUNTER, representing the Royal College of Physicians, said that since he had emphasized the importance of eliminating the small septic foci there had been a marvellous improvement in the condition of the teeth, the ears, the nose, and the throat of the people. Consequently he had pleasure in supporting the request of the deputation for periodical medical and dental examination.

Dr PORTS said that a great proportion of mental disease was due to abnormal physical conditions and disturbances which had existed for years unrecognized by the patient. In this country at present more beds were occupied by mental patients than by those suffering from physical disease. By removing various physical illnesses and disabilities the number of cases of insanity had been tremendously reduced, and in many instances cures had been effected by periodical medical and dental examination.

Mr R LINDSAY, representing the British Dental Association, endorsed the programme as set forth by the deputation from the People's League of Health. A great deal was being done at the present time under the additional benefits in connexion with national insurance, but they wanted money to do more. In reality it was an economic proposition, as it saved an enormous amount of after disease, which involved expense.

Mr E LAMING EVANS said many operations could be avoided if the detection of early symptoms of certain diseases were possible.

Dr C S MIERS referred to the taking of electrocardiographs, which provided an early diagnosis in heart trouble, and enabled employers to transfer men from arduous to less arduous labour. In one case he had pointed out that their diagnosis was far ahead of their treatment, and an employer had replied that it gave him a chance of saving men by transferring them to other occupations in heart disease, lung disease, and tuberculosis.

Dr R J LIFWELLYN spoke on the advantage of early diagnosis of heart disease, which was so prevalent in this country.

Dr E E FREMANTLE, M.P., remarked that the question, from a House of Commons point of view, of any proposal such as this, the carrying out of which would involve a very great expenditure, must necessarily be the economic one. It seemed to him that the examination on entrance to employment provided a sufficient precedent for enlarging the field of inquiry.

Viscount BURNHAM asked for the establishment of a special departmental committee to explore the means by which such periodical examinations could best be carried out, as a preliminary inquiry to the carrying out of such an important step towards the improvement of the public health. The deputation did not propose to deal with the second resolution in view

CROYDON COUNTY BOROUGH—Assistant Medical Officer of Health and  
District School Medical Officer. Salary £600 per annum.

### Meetings of Branches and Divisions

#### YORKSHIRE BRANCH LEEDS DIVISION

*Welcome to Medical Graduates*

A special meeting of the Leeds Division on July 1st held in the Library of the Medical School took the form of a conversation one to one with the medical student about to graduate.

Mr M. A. Abrams the successful candidate for the British Medical Association prize in the Durham Leeds and Sheffield Group was presented with the parchment certificate the money (£100) had already been handed over to him.

Dr A. HAWKARD J.P. Alderman of the City of Leeds in addressing the meeting gave reminiscences of the Leeds School of Medicine when he started his medical studies in 1899. He said that the school was then much smaller and different the student were a bit rough in manner what in for enjoyment and found it easier to learn and to take no prizes. He mentioned several of the teachers then in quite a humble position who subsequently became eminent. The surgeon of that date as a rule took private practice operated in a tweed suit and rarely touched the abdominal bands using the betterment of medical practice Dr Hawkward pointed out that the Midwives Act had diminished largely the drift of the profession. In club work the remuneration of the medical profession was very inadequate but since the Insurance Acts had been in operation they had been fairly decent and the prosperity of the profession had been much enhanced. Dr Hawkward related in what way the British Medical Association had in the interests of the profession greatly modified the original Insurance Bill and continued on the watch to protect the profession in the matter of insurance and in all other things relevant. It was therefore necessary that the Association should be strong and that position could be fully realized only with the whole profession on had joined its rank. At present the British Medical Association was recognized by the Government department as the only body that could authoritatively speak for the medical profession. Young medical men starting in life should look themselves. Is it to be work or pleasure. Most would decide for work last time could not be recovered. He would suggest that medical men for their own benefit and for that of everyone else should take more interest in public affairs and judging from his own experience he thought no medical man would regret participation in public work and in doing this duty and sticking loyally to his colleagues.

Dr WELSH in proposing a vote of thanks to Dr Hawkward for his address spoke from long experience of the good work that the British Medical Association had done and had in hand for the medical profession and of the great necessity and advantage of being a member of the Association.

A copy of the *Handbook for Recently Qualified Medical Practitioners* was presented to the graduates.

#### BIRMINGHAM BRANCH BROM GROVE DIVISION

The annual meeting of the Brom Grove Division was held at the Smallwood Hospital, Redditch on July 7th. The following officers were elected:

President: Dr E. D. Smith. Vice-President: Dr H. E. C. Dier. Secretary: Dr H. Warburton. Librarian: Dr H. Warburton.

On assuming the chair Dr PROTHMER DUFFY spoke warmly of the work done for the Division by its retiring chairman Dr HAWKIN and proposed a hearty vote of thanks which was carried.

unanimously. A vote of thanks was accorded to the House Committee of the Hospital for the use of the board room. At the close of the annual meeting a general meeting of the Division was held. The resolutions to be submitted to the Annual Representative Meeting were considered. With regard to Section 118 of Annual Report of Council it was considered that the wording of this paragraph was a little vague and the representative was instructed to vote for the recommendation provided that the words "for other administration on whatever the anaesthetic were meant to include the prolonged administration of nitrous oxide." With regard to paragraph (A) of this section of the meeting was of opinion that a fee of 10s. 6d. should be paid regardless of the number of patients dealt with on one occasion.

A discussion ensued on the programme of the Division for the year. The chairman and secretary were instructed to arrange for a course of lectures to be given to the Division during the early part of the month. The secretary was instructed to write to Dr Collier asking for a formal resolution with regard to anti-natal work in the Division.

#### SOUTH WALES AND MONTGOMERIE BRANCH SOUTH WEST WALES DIVISION

The annual meeting of the South West Wales Division was held at the Ivy Bush Hotel, Carmarthen on July 2nd. It was presided over by a luncheon given to the officers and executives by the retiring chairman Sir John Lynn Thomas K.B.E. (C.B. CMG F.P.C.). The work of the Division in its efforts for medical charities was considered highly satisfactory and the honorary secretary was asked to convey the thanks of the Division to Dr T. P. Davies the charity steward.

At the general meeting in the unavoidable absence of the chairman elect Dr D. H. Pennant D.S.O. the retiring Chairman remained in the chair. Dr Pennant was elected chairman and Dr A. H. D. Smith M.C. was re-elected honorary secretary for the year 1927-28.

The honorary secretary was instructed to write to headquarters a list of future year's condensed agenda for the Annual Representative Meeting could be sent to Divisions one month before the date of the Annual Representative Meeting. The representative was asked to pay special attention to the motions at the Annual Representative Meeting re certification of mental cases and methods of safeguarding practitioners in certifying cases. He was instructed to support the British Medical Association motion on appeal tribunals for panel practitioners against his findings of the Ministry of Health. There was a strong feeling at the meeting that the attendance at meetings particularly those at which lectures were given by prominent members of the profession was no satisfactory and the honorary secretary was asked to circulate the Division and ask the members to be more active in their attendances. The difficulty is of course the wideness of the Division which covers three counties.

#### SOUTH WESTERN BRANCH

The eightieth annual meeting of the South Western Branch was held on June 22nd in the Library of the Royal Devon and Exeter Hospital when the president Dr P. H. Wages was in the chair. There was a fairly large attendance.

The annual report of the Branch Council for the year 1926-27 and the annual financial statement for 1926 were presented by the Branch Secretary. The report and financial statement were adopted. It being the turn of the Barnstaple Division to choose the president elect it was with great pleasure that he meeting heard that Dr J. P. Harper O.B.E. had been nominated for the position. On the motion of the Chairman Mr P. D. Warburton was unanimously re-elected Branch honorary secretary and treasurer. Dr P. H. Wages then resigned his chair and introduced Colonel Ransom P.J. as the president-elect who was greeted with acclamation. Colonel Ransom replied conveying his sense of the honour paid him by the Branch and proposed a hearty vote of thanks to the retiring president.

for his services in the interests of the Branch during his year of office and further proposed a resolution that he be created a vice-president of the Branch. The motions were carried by acclamation, and Dr WAGNER thanked the meeting.

Colonel PICKARD delivered his inaugural address on 'Atheroma of the arterial arteries—a comparison between the brain and the eye.' This extremely interesting work was based very largely on the president's own observations. He showed many interesting charts of the field of vision, and pointed out the frequency with which it was possible to draw conclusions as to the condition of the general circulatory apparatus from the observations made by the ophthalmoscope. The address impressed the audience considerably. The paper was illustrated by means of the epidiroscope. A hearty vote of thanks to the president for his address closed the meeting.

In the evening the annual dinner of the Branch was held. The attendance was small but a very enjoyable evening was spent. Ladies as well as medical and non medical guests were present.

#### SUFFOLK BRANCH WEST SUFFOLK DIVISION

A MEETING of the West Suffolk Division was held at the West Suffolk General Hospital, Bury St Edmunds, on June 28th, when Dr GRACE GRIFFITH was in the chair.

Arising out of the minutes, the SECRETARY reported that in regard to the Coroners Act he had been in communication with the coroners for the county and the borough, and that the latter had agreed that 10/- 6d should be paid for a report by a doctor which enabled a coroner to dispense with an inquest, and also that a mileage fee of 3d a mile each way would be paid to doctors in the county attending inquests in the borough. The coroners for the county had not yet been able to find out whether the county council would be prepared to make a similar payment. In regard to registration of maternity homes the county medical officer of health had been communicated with, and had stated that no action had been taken by the county council at present, but that if the matter became a live question he would bear in mind the request of the Division.

The Annual Report of Council was discussed. Dr BARWELL introduced the sections dealing with preliminary, finance, organization and BRITISH MEDICAL JOURNAL. He drew attention to the fact that the Annual Meetings of the Association would be held as follows: 1928 Cardiff, 1929 Manchester, 1930, Winnipeg. In regard to the establishment of a locum bureau, the Division approved the action of the Council, and instructed the representative to oppose the motion criticizing the Council's action which was to be moved by Gateshead. Dr Barwell gave a very good summary of the financial position of the Association, which was generally considered to be satisfactory. The formation of groups in the Association was considered, and the representative was instructed to vote in favour of the recommendation of Council on this heading (SUPPLEMENT, April 23rd, p. 140). Dr Barwell also explained in detail the decisions of Council in regard to local conferences, the organization of the profession in South Africa and the present financial position of the BRITISH MEDICAL JOURNAL.

Dr HINELL, in dealing with the paragraphs on science, medical ethics, medico-political and parliamentary elections, drew attention to the fact that library books may now be retained for twenty-eight days instead of fourteen, as had previously been the case. The position as regards pathologists was discussed at some length, and the representative was instructed to support the resolutions of Council on page 145 of SUPPLEMENT of April 23rd. He was also instructed to vote in favour of the recommendation in regard to professional disputes (SUPPLEMENT June 25th, p. 252). Under the heading of science the proposed scheme for collective investigation was considered and approved, and the representative was instructed to vote in favour of the recommendation of Council appearing on page 252 of SUPPLEMENT of June 25th.

A considerable discussion took place about the coroners law and the new arrangements for death certification. The representative was instructed to vote in favour of the recommendation of Council on page 147 of SUPPLEMENT of April 23rd with regard to practitioners engaged in municipal maternity hospitals, and also the recommendations on page 148 with regard to anaesthetics. The position of medical officers of public schools was considered, and all the recommendations of Council appearing on page 150 were approved. In regard to parliamentary elections, after some discussion it was decided to support the recommendations of Council appearing on page 254 of SUPPLEMENT of June 25th.

Dr GRACE GRIFFITH introduced the sections dealing with public health and Poor Law, Poor Law reform and national health insurance. The question of public education in health matters was discussed at some length, and it was decided finally to instruct the representative to use his own discretion in regard to the recommendation of Council (SUPPLEMENT, June 25th, p. 255). It was felt that the Division was not sufficiently convinced of the benefit to the public of the whole of the programme suggested to pledge itself at this stage to the Council's recommendation. The representative was instructed to vote in favour of the recommendation that health lectures by medical men should be paid for (SUPPLEMENT, April 23rd p. 151). The information given by the Council under the heading of ophthalmic benefit was carefully considered, and the representative was instructed to vote against the recommendation of Council appearing on page 256 of SUPPLEMENT of June 25th as it was felt that the position at present was very chaotic and that it would be unwise for the Association to pledge itself to the support of an arrangement for treatment at clinics. The Division was of opinion that the matter requires further consideration before any decision is made.

Dr SHAW introduced the paragraphs dealing with hospital, naval and military, medical benevolence, and Wales, Ireland and the Overseas Branches. The recommendation on page 155 of SUPPLEMENT of April 23rd in regard to payment of visiting staff was approved, and the representative instructed to vote in favour of it, although it was felt that no action would probably need to be taken on this matter locally at present. The recommendation of Council regarding the treatment of early mental disease (April 23rd, p. 155), was left to the discretion of the representative. The appendix in connection with contributory schemes (SUPPLEMENT, April 30th, p. 184) was considered and approved in principle.

#### ULSTER BRANCH NORTH EAST DIVISION

A MEETING of the North East Division of the Ulster Branch was held in Coleraine on June 6th, when Dr H. S. MORRISON, M.P., was in the chair. It was the largest meeting the Division has ever held. Dr A. F. HUNT of the New Forest Clinic was to have addressed the meeting, but owing to the illness of his daughter he could not be present. Dr R. MARSHALL, visiting physician, Ulster Hospital for Children, Belfast, deputized and read a paper on the prevention and treatment of rheumatic heart disease in children based on his experience at the Ulster Hospital for Children and Women, Belfast. He discussed the importance of minor manifestations of rheumatism, particularly "growing pains," slight inactivity, undue fatigue, loss of weight and twitching of the face and limbs, the value of electro-cardiography and radiography as a guide to diagnosis and prognosis, statistical evidence as to the effects of tonsillectomy in rheumatic cases, and urged the prolonged administration of sodium salicylates in moderate doses, even in the apparently quiescent period. In conclusion he emphasized the need for a vigorous campaign against rheumatism, the provision of recovery hospitals for city children, of supervised education and vocational training, and suggested that Northern Ireland is a suitable area for the closer study of the disease by a period of compulsory notification.

It was unanimously resolved that the name of the Division be "The North East Division, Ulster Branch."

July 20, Wed	Council (Edinburgh) Conference of Honorary Secretaries (Edinburgh)
	Meetings of Sections etc Edinburgh
July 21 Thurs	Meetings of Sections etc, Edinburgh
July 22, Fri	Meetings of Sections, etc., Edinburgh
	ALFRED COX, Medical Secretary.

#### BRANCH AND DIVISION MEETINGS TO BE HELD

METROPOLITAN COUNTIES BRANCH HAMPSHIRE DIVISION.—A meeting of the Hampshire Division will be held at Hampshire General Hospital on Thursday, July 14th, at 8.30 p.m. to discuss the Supplementary Report of Council (BRITISH MEDICAL JOURNAL SUPPLEMENT, June 25th, 1927) and to give instructions to the representatives at the Annual Representative Meeting. Members are requested to bring the above mentioned SUPPLEMENT to the meeting. Coffee.

### National Insurance.

#### EXTENSION OF MEDICAL BENEFITS TO INSURED PERSONS (IRISH FREE STATE)

The committee appointed to report on the position of national health insurance and medical services in the Free State has issued its final report. It consisted of nine members, seven of whom signed the majority report, but two of whom signed with reservations. A minority report is signed by two members of the committee who differ from all the essential recommendations of the report or the majority, especially with regard to the provision of medical benefits for uninsured persons. The following is a summary of the main recommendations in the majority report.

#### National Health Insurance

- The termination as from December 31st, 1927 of the National Health Insurance (Prolongation of Insurance) Act 1921.
- The extension of medical benefit to insured persons with an increase of 2d in the existing weekly contribution rates to be borne equally by the employer and the employee.
- The diversion to medical benefit of the monies set free from insurance funds consequent on the abolition of insurance com-

mittees and the transfer to local authorities of responsibility for the treatment of insured persons suffering from tuberculosis.

(2) The payment by the State of compensation to local authorities in view of the additional burden placed on their funds by the transfer to them of responsibility for the treatment of insured persons suffering from tuberculosis.

(3) The provision of four whole time district medical officers on a permanent basis in connexion with the national health insurance scheme.

#### Poor Law Medical Services

(1) The extension of the dispensary nursing service especially in the 3 areas on the western board which are not already covered.

(2) The provision by the State of substantial aid towards the cost of erecting, remodeling and reconstructing central dispensaries as and where required.

(3) The remission or refundment (in whole or in part according to the circumstances) of taxes incident to motor usage in the case of doctor, nurses and midwives engaged in the public service in rural areas.

(4) The extension of the Education (Provision of Meals) (Ireland) Act 1917 to rural districts.

(5) The provision of financial assistance for the construction, modernization and equipment of county and district hospitals and institutions.

(6) The establishment of a national (dispensary and hospital) medical service.

(7) The recompense by the State of one-half of the salaries of the county medical officers of health.

(8) The setting up of a standing council to advise and assist the Minister of Local Government on health matters.

(9) The appointment of a small committee of scientific experts to devise a scheme of medical research suitable for the Irish Free State.

These recommendations are not signed by Mr. J. J. McIlhenny, Assistant Secretary to the Ministry of Finance, and Mr. J. Hurson of the Local Government Department.

Dr. E. F. Stephenson, Chief Medical Officer to the Department of Local Government and Public Health, in a separate memorandum, defines his opposition to the extension of medical benefits for insured persons mainly on the grounds that they are receiving for the most part, medical treatment under the Medical Charities Acts.

Dr. R. J. Rowlett, whilst signing the majority report states in a memorandum that he agrees with his colleagues in all except their decision not to recommend the immediate establishment of a State medical service.

In proposing the solution that they regard as ideal, he says, my colleagues seem to have lost sight of the general principle to which they commit themselves in the closing words of their report—namely that the health of the people is a prime consideration and that economy secured at the expense of the people's health is prodigal waste of a national asset. The almost unique position held by the Irish Free State as regards population makes the danger of subordinating health to pecuniary considerations greater here than in other countries. The Irish Free State is losing its population at a more rapid rate than any country in the world except one.

Emigration does more than deprive the country of a certain number of citizens. It takes away probably the 3 who are the most energetic and healthiest of the people. For equal figures of emigration, therefore, is a more serious loss to the country than death. With a population gradually dwindling long in strength even more than in number, it is necessary to take every possible step to protect the health of those who remain. The failure to take proper measures for the preservation of health in the case of the nation as a whole, or the individual often cost more in actual expenditure than if such measures had been taken. The demand for an efficient health service stands however on higher grounds than can be expressed in pounds, shillings and pence. As the health of a man is his most important asset, so the health of a nation is its most important asset, and the care of health is one of the first duties of Government. Dr. Rowlett concludes by recommending that steps should be taken at once to establish a comprehensive scheme of medical services such scheme to apply both to insured persons and to those who have a claim to treatment under existing legislation.

#### COVENTRY LOCAL MEDICAL AND PANEL COMMITTEE

The report of the Coventry Local Medical and Panel Committee for the year ended May 31st 1927 has lately been issued.

Discussing prospective legislation it says that the prospect of any fulfilment this or next year of the major recommendations of the Royal Commission on National Health Insurance is now doubtful. It is possible however that a bill may be introduced late in the autumn session standardizing ophthalmic and dental benefits which are at present in a most unsatisfactory condition. The Panel Committee has circulated local practitioners recommending that in the statement which is required to be given free on request to a member of a society providing ophthalmic benefit consultation with an ophthalmic surgeon should be prescribed. It does not follow however that the society will act upon such recommendation as under the majority of current schemes they can send their member direct to an optician and merely make a payment towards the cost of glaze.

Negotiations respecting the capitation fee will be in progress towards the end of the year and the Panel Committee, consider

ing, it highly important that the Insurance Acts Committee of the British Medical Association (the officially recognized negotiating body) shall have available the true facts regarding practice expenses and work done has twice circularized local practitioners asking for any available practice statistics, to be furnished to headquarters. The Panel Committee considers that unity and efficient organization is more necessary than ever and it proposes continuing the annual contribution of approximately a halfpenny capitation fee towards the National Insurance Defence Trust.

Under the heading economy in prescribing the report says: The Government have concluded arrangements with the chemists whereunder the whole of the Drug Fund—now a definitely fixed sum of about 2s. 10d. per insured person—shall be administered by the Retail Pharmacists' Union on the chemists' behalf. This means that in the event of the year's bills at current tariff rates being in excess of the fund individual chemists' accounts will be discounted. If through the attainment of economies the Drug Fund is in excess of the bills the chemists will take an extra margin of profit. Whether this arrangement is ethically desirable or even practically expedient will doubtless afford ground for a good deal of debate and the attitude of our leaders is not yet known. But the liability of chemists to have their bills discounted will undoubtedly evoke an economy campaign in the near future. It therefore behoves every practitioner to give fullest consideration to every reasonable step which may tend towards saving unnecessary expenses in prescribing in order that a firm stand may be taken on the principle of the doctor having a free hand in the ordering of any drug or medicine which he considers essential in his patient's interest.

In regard to certification and excessive sickness claims the report notes that the past year has undoubtedly taken an altogether unlooked for toll of the approved societies' funds. While the Panel Committee finds no evidence that laxity in the granting of certificates exists in Coventry it emphasizes the point that the national insurance chemist, based on the actual fact as a criterion for the issue of a certificate is inability for work, and no considerations of difficulty in obtaining suitable work ought to enter into the question seeing that appropriate public provision is made under the Unemployment Insurance Act and Poor Law for cases which are clearly outside the scope of the National Health Insurance Act.

## Correspondence

### Periodical Medical Examination

SIR—Panel practitioners will unite in thanking the Minister of Health for giving a definite quietus to the deputation of the People's League of Health which waited on him on June 28th.

As reported in the SUPPLEMENT of July 9th (p. 18) this group of theorists wants us to examine periodically all persons on our lists. I am certain that no one of the deputation is a panel practitioner and I question if the members ever visualized what such an examination to be of any value must entail. One speaker laid stress on the detection of hidden foci of infection in the teeth, another on the early recognition of heart disease. Assuming that the wish of the League became an order should we be entitled to order an x-ray of the first, or an electrocardiographic examination of the second? Who would pay for them? Without such provision any examination is going to be of little value.

On the other hand, if the order empowered us to have the aids it is safe to assume that there would be a heavy penalty for us if we did not use them and equally the chance of being called to account if we used them too frequently.

I apologize for trespassing on your space to point out these, to us obvious objections. The Minister killed the suggestion. Let us hope the People's League of Health will have the good sense to bury it and forget it—I am, etc.,

Stokeport July 11th

F. J. KITT

## Naval and Military Appointments

### ROYAL NAVAL MEDICAL SERVICE.

Surgeon Vice Admiral Sir Joseph Chamberlain, KCB, CMG, is placed on the retired list.

Surgeon Rear Admiral A. Cassell, CB, OBE, to be Surgeon Vice-Admiral.

Surgeon Rear Admiral A. R. H. Skeel, placed on the retired list.

Surgeon Captain H. C. White, M.D., to be Surgeon Rear Admiral.

Surgeon Captains L. M. Morris, OBE, and A. McCloy, to the Victoria for R.N. Hospital, Ha-lar.

Surgeon Commander P. D. Ramsay, placed on the retired list with the rank of Surgeon Captain.

Surgeon Commanders R. Buddle, OBE, to the Tamar for R.N. Base, Singapore; temporary L. Warren, OBE, to the Columbine for R.N. Hospital, Queen's Ferry.

Surgeon Lieutenant J. G. Holmes, to the Cicala, temporary.

Messrs B. J. Scott, T. S. O. Lorne, J. J. Keen, and P. W. Gayford have entered as Surgeon Lieutenants for short service and been appointed to the Victoria additional for R.N. Hospital, Ha-lar for course of instruction.

The following have entered as Acting Surgeon Lieutenants and been

## British Medical Association: Annual Meeting, Edinburgh, 1927.

### ANNUAL REPRESENTATIVE MEETING

*Friday July 15th*

THE Annual Representative Meeting opened in the McEwan Hall of Edinburgh University on Friday, July 15th, 1927 at 10 a.m. Dr H. B. BRACKENBURY (Chairman of the Representative Body) was in the chair supported by Mr R. C. Hogarth (President), Sir Robert Bolam (Chairman of Council), Mr Bishop Harman (Treasurer), Dr Alfred Cox (Medical Secretary) and Mr Ferris-Scott (Financial Secretary), with other officials of the Association.

#### THE ROYAL PATRON

AS SOON as the meeting was fully constituted the CHAIRMAN moved

That the British Medical Association meeting in Edinburgh at the time His Majesty the King is in residence begs to present its humble and loyal duty to the Patron of the Association and to Her Majesty the Queen.

This was carried with cheers, the representatives standing.

#### PRELIMINARY BUSINESS

The returns of representatives and of acting deputy representatives were received and entered on the minutes, and some apologies for absence were read.

The standing orders as adopted at Nottingham 1926 were readopted subject to one amendment moved by the CHAIRMAN, relating to Standing Order 46 governing the election by the meeting of eight members of Council (as distinct from the twelve members elected by grouped representatives). He proposed that the standing order be amended to provide that only

those who had for at least three years been members of the Representative Body—namely appointed representatives, deputy representatives acting and members of Council—should be eligible for election among the eight members of Council. He had consulted the Organization Committee with regard to this change, which involved a slight restriction of the field of nomination. As the matter stood at present there was perhaps too great a likelihood of somebody who had not himself done a great deal of work for the Association being nominated and getting elected more or less by accident. He now brought forward this slight restriction of the field of nomination. On the one hand, it was desired to reserve the eight seats on the Council for those who had done some conspicuous service to the Representative Body; on the other, it was quite possible that the Council might during the year have done something to which the Representative Body had a very strong objection, and the Representative Body might wish to mark that objection by turning out the eight elected representatives and putting in eight others. Therefore he proposed the condition that instead of the three years membership of the Association the necessity of three years membership of the Representative Body—not necessarily the three previous years, should be imposed.

The amended standing order was agreed to.

A new standing order was also agreed to whereby new members of the Representative Body would be formally introduced to their fellow members at the first meeting attended by them and invited to sign the permanent record book of representatives.

The CHAIRMAN in moving this standing order said it was thought that there should be a permanent record of those who had been members of the Council or representatives. Two

books had been prepared, and it was desired that every member of the Representative Body should sign and new members add their signatures from year to year, and be presented by the Chairman to the Representative Meeting.

It was further agreed that the section of the agenda concerning the building extensions at the London headquarters should be considered as first business after lunch, the representatives to meet for that purpose in the Anatomical Theatre in order that a demonstration of the proposed extensions might be given. The section under "Oversers Branches," it was also agreed, should be taken as the first business on Monday afternoon, the remainder of the agenda to be taken in the order in which it was printed.

It was also agreed that the engagement by representatives of seats for the meeting previous to its commencement should be limited to a seat for the representative himself and for the other representatives, if any, of his constituency, this to be operative at the present Representative Meeting.

#### CIVIC WELCOME

At this stage in the proceedings a civic welcome to Edinburgh was given by the Right Hon. the Lord Provost (Mr. Alexander Stevenson), who was accompanied by the Town Clerk (Mr. Andrew Grierison), and the City Chamberlain (Mr. Robert Raton), and by Sir Robert Philip, President-Elect of the Association.

The CHAIRMAN, on behalf of the Representative Meeting, expressed great pleasure at the visit of the Lord Provost.

The LORD PROVOST said Mr. CHAIRMAN, ladies, and gentlemen, on behalf of the corporation and citizens of Edinburgh I desire to accord to you all a very hearty welcome to our city. I may add that I sincerely appreciate the privilege of greeting the members of this distinguished Association. I understand that on three previous occasions you have met in Edinburgh, namely, in 1858, in 1875, and in 1898. After a period of twenty-nine years we are delighted to welcome you back again, not only because you belong to a profession associated with the preservation of the health and well-being of the nation, but because we in Edinburgh have a special regard for, and pride in, the medical school of our city, whose sons have borne the torch of learning to all parts of the world and whose teachers have, by their skill and knowledge, won for themselves the highest places in the ranks of your profession. The meeting has a special significance from the fact that it coincides with the centenary of the birth of Lord Lister, whose epoch-making work was largely accomplished in our city, and to whose genius the world owes so much. In conclusion I would only say that I trust that your meeting will be as successful as former meetings, and that your deliberations will be distinguished by the same breadth of vision and of wisdom as that for which they have been noted in the past.

The CHAIRMAN, on behalf of the members of the meeting, assumed the Lord Provost of their gratitude to him for his kindly words of welcome. His lordship had reminded them of the historic importance and value and influence of the Medical Faculty of the University. They were universally recognized throughout the profession. If it was true that no assembly could altogether escape the subtle influences of its environment, the deliberations of the members would be characterized not only by that breadth of vision and wisdom to which his lordship had made reference, but by all the dignity and the learning and the substantial solidity which Edinburgh exemplified.

The LORD PROVOST briefly acknowledged the remarks of the Chairman, and then withdrew.

#### ANNUAL REPORT OF COUNCIL

##### The Presidency

The Annual and Supplementary Reports of Council having been received, the CHAIRMAN OF COUNCIL moved, and it was unanimously agreed, with applause, that Sir Ewen Macleay, M.D., F.R.C.P., F.R.S.E., be elected President of the Association, 1928-29.

Sir Ewen Macleay, who was cordially received, expressed his grateful thanks to the Council for their nomination. It was a great honour to be made President-Elect. He rather prided himself upon the fact that it was the first time a previous Chairman of the Representative Body had been accorded this high honour. Perhaps it was appro-

priate that this should happen in the case of a representative from Wales, because the Representative Body was born in Wales. It came to light in the Principality in 1903 at the Swansea meeting. (Applause.)

It was also agreed unanimously that Dr. F. G. Thomson, Past President, be elected a Vice-President of the Association in recognition of his presidential services in 1925-26. Dr. Thomson, who was received with applause, briefly expressed his appreciation of the honour done him.

#### Annual Meetings, 1929 and 1930

The recommendation of Council that the Annual Meeting in 1929 be held in Manchester was agreed to.

The further recommendation of Council that the Annual Meeting for 1930 be held in Winnipeg, Canada, was next moved. Sir ROBERT BOLAM explained that the reason for this unusual motion before its time was that if they went to Canada in 1930 the arrangements would take considerably longer to carry through than those for a meeting in Great Britain. Therefore the Representative Body was asked to implement this resolution at an earlier date than usual. The recommendation was agreed to.

#### The Jenner Museum

On the remainder of the Annual and Supplementary Reports under "Preliminary," Sir ROBERT BOLAM said that the Council had been reluctantly compelled to refuse the kind offer of Lord Berkeley in regard to the proposition to set up a Jenner museum in the house at Berkeley, but a member of the Council who held high civic rank in the locality, were taking steps to see if the local profession could not manage what as a Council they had not felt it advisable to undertake. He believed that something might yet be done.

#### Locum Bureau

Sir ROBERT BOLAM went on to speak of what had been done in the matter of locum bureau. The Council had not been able to do exactly what the Representative Body had instructed in 1925. It seemed to the Council that the question of dealing with locumtenents was only a very small part of the service which practitioners required in this direction, and the least remunerative, and, consequently, for Headquarters, the most expensive work came in. The remunerative portion of medical agency work came in with regard to transfer and partnerships. There were certain difficulties in the way of the Association qua Association trading, and it seemed best to the Council that they should seek out one of the reputable agencies and see if they could not, by obtaining an interest therein, exercise an influence on policy which would mean that the agency work would be conducted on lines approved by the profession generally and as a business transaction. They were able to acquire on favourable terms a holding in one of the best known agencies, and one having a very high reputation for integrity and business-like dealing—the Scholastic, Clinical, and Medical Association, Ltd.—and that body had arranged that one half of the directorate should be nominated by the British Medical Association. The members who had been placed on the directorate in consequence of this arrangement were the Treasurer (Mr. Bishop Hamman), the Chairman of the Organization Committee (Dr. Morton Mackenzie), Sir Humphry Rolleston, a very old and valued friend of the Association, and himself (Sir Robert Bolam). The negotiations having only just been completed, they had not yet been able to explore the possibilities of associating the bureau in various parts of the country for local purposes. Preliminary investigations had been made, particularly in the North, and he hoped that by the next Representative Meeting they would have done all that the Representative Body had permitted them to do. By resolution the Council had permitted the name "British Medical Association Bureau" during the time of such association, and henceforth it would be conducted on business lines, give good services, and expect the usual return. The Association held a very large block of shares and would participate in dividends. There were difficulties in accomplishing the work in any other way.

Dr R. Loazes (Gateshead) had a motion on the agenda declaring that the Council had exceeded its instructions with regard to the formation of bureaux for the provision of documents and assistants under the auspices of the Association, these instructions were in the form of resolutions of the Annual Representative Meeting 1925. He said these instructions specifically directed the Council to set up an organization that would be within and under the control of the British Medical Association. Action had been taken and arrangements forwarded about which the Representative Body had not given to the Council specific instructions. Gateshead recognized the insuperable difficulties and that the Council had done in the circumstances the only effective thing possible, but there was an underlying basic principle or power involved that was dear to the Representative Body. The Council was composed of the Association's intelligentsia and very seldom erred but the Representative Body ought to have had a further say in the matter. Before the Association launched out into competitive business before choosing the particular body with which they allied themselves and before they gave to it the name of the British Medical Association and purchased shares the Representative Body should have been consulted and had a voice in so grave and important a matter.

The Chairman of Council said the amendment was something that all members of the Council would deplore more than anything else—a vote of censure by the parliament of the Association. Dr Forbes had acknowledged that the instructions of the Association could not have been fulfilled in any other way in the circumstances, and therefore he felt the Council was in great degree exonerated. Intramural work particularly finance, was committed to the Council during the year and the elected members of the Finance Committee were the watchdogs of the Representative Body. Such transactions as had just been completed could not be canvassed in broad daylight or wait for the Representative Meeting nor were they of such magnitude as to demand a Special Representative Meeting. Having explained the circumstances and Gateshead having registered their protest as good constitutionalists, he hoped the amendment would not be passed.

Dr PETER MACDONALD asked Gateshead to withdraw the amendment.

Dr FORBES asked leave to withdraw his amendment and this was done.

#### *The Solicitor to the Association*

SIR ROBERT BOLAM moved as a recommendation of Council that Mr W. E. Hempson, in recognition of his faithful and devoted service as Solicitor to the Association for twenty-seven years be elected an honorary member of the Association. It gave him much pleasure he said to ask members to voice their recognition of one who for long years had been of great value to the Association in his professional capacity and a friend at the Annual Meetings (Applause). They would all echo the wish that Mr Hempson's striking figure would be seen at meetings for many years and that his complexion would never grow less tanned or his voice less jovial (Applause).

The Chairman said that he was very glad indeed to associate himself with what the Chairman of Council had said and he was sure that he was speaking on behalf of the whole of the Representative Body in saying that they agreed very emphatically with it.

The motion was carried with much enthusiasm by the members rising.

Mr HEMPSON said that every opinion he had given to the Association during the time that it had been his privilege to act for it had been a considered one. It was so in the present case. There was a fineness of time for all things and there was a time of stress for everyone. The latter must be anticipated the former must be acted upon. He had not officially been the Solicitor of the Association for twenty-seven years. It was his privilege to act for it uniformly but at the same time professionally for three years before that. He had therefore completed thirty years' service in the Association. That fact led him to the conclusion that a man was wise to go while he was still wanted and not to reach the time when his departure was

desired. This induced the decision which he had conveyed to the Chairman of Council—namely, that on receiving notice of his reappointment this year he should not ask for his reappointment to be considered next year. He therefore was in the most delicate position that until April or next year he would be a member of the Association and at the same time its Solicitor a dual position which, he thought no man in his profession had been privileged to enjoy. The Representative Body was partly his creation. He was brought in to represent the Association and the Constitution Committee was sitting. There were two brains in that connection that were indelibly fixed on his mind. One was that of Edmund Owen, and the other was that of Sir Victor Horsley. He acknowledged that the Association had done him a high honour not only by electing him but by, perhaps, the highest honour that could be conferred upon him because not only was it conferred upon the recommendation of the Council but it came from the whole body of members in confirmation of that recommendation and as voicing the opinions the views and the wishes of the British Medical Association throughout the world (Applause). Mr Hempson was too much affected to conclude what he had intended to say.

#### ASSOCIATION FINANCE

Mr BRISTOL HUTTON (Treasurer) moved, on behalf of the Council approval of the portion of the Annual Report under Finance. He said he was pleased to be able to present an exceptionally good balance sheet. The expenditure had been heavy but the receipts had been heavy also, which was due to the large increase of the membership this year. This explained an apparent mistake which had been made in the preceding year. A surplus of £4,000 had then been budgeted for. The actual surplus was £8,660. That surplus had been utilized in a fashion which would be seen indicated in the balance sheet. Under Reserve Fund it would be seen that there was carried forward Investments of £23,000 and there had been added to that in the year 1926 £6,000. Of that amount some £3,600 was replacement of investments realized in the preceding year for the payment of the new premises and a sum had been added making £6,000 which was the re-creation of and increase of the reserve fund. In addition a sinking fund had been formed for the redemption of the leasehold premises. The new House stood in the Association's property for 200 years at the end of which time the Association's rights and privileges in it would cease. It was therefore right that the Association should look forward to the future, so that succeeding generations should not be put into a worse position than the present when it had inherited the time and which had been handed over to it. A sum of £1,000 had therefore been allocated for the formation of a sinking fund which sum would be added to year by year so that at a certain date the value of the premises would be returned to the Association in cash.

Referring to the list of investments (the Treasurer continued) the first of those was a new investment a sum of £5,220 which was the purchase price of the shares in the Medical Agency. The actual sum paid was £4,050. The balance was shown on the liability side of £1,170 which would be paid at some future date when the present holder of those shares desired that they should be sold to the Association or actually. The Association held the transfer, but had not paid for the shares. The Association was in possession of all the rights which appertained to those shares with the exception of having paid for them and of the dividend which accrued.

Dealing with Abstract B the members would notice that the item charges on bank loan, which in 1925 was £2,783 had been reduced in 1926 to £657 and at the present time he was pleased to announce that there was no bank loan at all in fact there was a small deposit.

After briefly reviewing the items contained in Abstracts C and D and turning to Abstract G the Treasurer said that last year had been a year of great financial difficulty in all matters of finance and of trading owing to the disturbances caused by the general strike, but despite that formidable attack upon the maintenance of the Journal (which for the first time in its existence had had to suspend publication), there had been a bumper

year in all items except one—sundry sales of the *JOURNAL* had declined by £500. Actually that was a favourable sign, because the greater the increase in the membership of the Association the smaller must be the number of non-members desiring to purchase the *JOURNAL*.

Referring to the deficits mentioned in Abstracts "H" and "I," he pointed out that the expenditure in connexion with those periodicals—*Archives of Disease in Childhood* and *Journal of Neurology and Psychopathology*—was, in a way, expenditure on scientific work, and therefore would never bring in any revenue. It was not anticipated that it should. If it did, it would immediately be expended on improving the quality of these journals. With regard to the Office Staff Superannuation Fund, the balance sheet showed that the total sum now invested in this fund was £16,830, but he was pleased to say that on December 31st the value of the investments stood at £17,622.

That, said the Treasurer in conclusion, completed the account of his stewardship during last year. There were points to which the attention of the members should be directed, such as the budget for the present year. They would see a statement of the estimated receipts, which it was expected would be slightly in excess of those of last year, and the estimated expenditure, which would be about the same as last year. A surplus was estimated for of £2,280, and if again a large increase in membership was experienced that surplus would be greater.

Dr F C MURLEY (Kensington), after congratulating the Treasurer on the very excellent return he had submitted, said no reference had been made to the Exhibition Fund of the Association. The Association ran an exhibition at the Annual Meetings, which must cost money, and in connexion with which there must either be a favourable or an unfavourable balance resulting. He had made inquiries in various quarters and had found that on some occasions there had been a deficit and on other occasions a surplus. He thought it desirable that information should be given with regard to the point.

Mr BISHOP HARRIS, in reply, said that the Annual Exhibition sprang up as a local effort, and although now managed from the head office, technically it did not count as Association work. The exhibition accounts had never been amalgamated with the general finances of the Association. The exhibition was an expensive business, and the Financial Secretary spent a great deal of time and went to considerable trouble in securing a really first-class exhibition, for it was an integral part of the Annual Meeting. The accounts were audited every year, and a statement of the balance was laid before the Finance Committee, but the accounts were not incorporated in the general accounts.

The Annual Report under "Finance" was approved.

## ORGANIZATION

### Formation of Groups in the Association

Dr MORTON MACKENZIE (Chairman of Organization Committee) moved as a recommendation of Council the approval of the scheme for the formation of groups in the Association, as set out in Appendix III to Annual Report (SUPPLEMENT, April 23rd, p. 158), and an instruction to the Council to prepare the necessary amendments to the Articles and By-laws for submission to the next Annual Representative Meeting, immediate provisional effect to be given to the scheme if need arose. He said that while they might be justly proud of the system of organization in the British Medical Association, and believed that it was probably the best model for an organization of its kind, they were only too glad to make it better if they could find a way. In this sense, the groups they thought they had found a way. The constitution of the Association was founded on a large number of local bodies of practitioners, each of which sent one of its members up to the Representative Meeting with resolutions and instructions. The Council, which was largely elected territorially, was charged with carrying out the policy and decisions of the Representative Body, and reported to the Representative Body each year what it had done or proposed to do. This system had

worked quite well in the past, but with increasing membership and the inclusion of a larger percentage of men engaged in various types of medicine, small groups or members occupied in the whole- or part-time practice of some special branch had fancied or had actually found that they could not make their voices heard under the present constitution. Sometimes in the past this had been met by special arrangements, originally with regard to the Services, and recently with regard to the medical officers of health. These special arrangements, however, took some time to organize and to go through the necessary legal procedure. The delay had led to these special members forming organizations of their own, outside the British Medical Association. It was desired now to provide some machinery whereby isolated members in certain classes might feel that they had some means of expressing their views without forming an outside association. The urgency of this question had been demonstrated during the last few months by the pathologists and spa practitioners respectively forming bodies of their own. Dr Mackenzie then went in detail through the scheme for group formation as explained in Appendix III of the Annual Report. The cardinal point of the scheme was that these groups should not be formed unless it was proved that the ordinary machinery of the Association could not be used. It was discussed in the Council whether the petitioners must be required to reach a certain number, but it was eventually decided that the proper criterion was, not the number of members who wished to form a group, but whether they could or could not make their voice heard through the routine organization. It was desired that these men should feel themselves to be a definite part of the Association, and therefore they should have the annual meeting of their group at the same time as the Annual Meeting of the Association. It was proposed to attach each group to its appropriate Standing Committee, the majority of them would probably come under the Medico-Political Committee. He believed that the scheme would work out to the advantage of the Association. Any threat of interference with the existing constitution had been carefully watched and admirably guarded against.

Dr C H MILBURN (Harrigate) moved to substitute for paragraph 4 of the scheme, which provided that a list of those qualified to be members of a group should be made in the central office, a provision that, subject to the approval of the Council, the executive committee of the group should define the qualification for membership. He said that it was felt that the executive committee of every group would be in a better position to realize what should be the qualification of membership than could any committee of the Association. No two groups were like there was a very large number of different branches of the profession, all having different qualifications.

Dr MORTON MACKENZIE said Dr Milburn had not met the difficulty he had mentioned. There must be a list of the group before an executive committee could be formed. The office must make the first list, and would afterwards take the definition of the group committee, subject to the approval of the Council.

Dr MILBURN was willing to modify his amendment so that it became a reference to the Council for consideration, and Dr Mackenzie accepted it in this form, the meeting agreeing.

Dr MILBURN also desired to amend paragraph 5 of the scheme, which provides that the annual meeting of the group shall be held at the time and place of the Annual Meeting of the Association, he wanted to insert the words "or, if found inconvenient, at such other time as the executive committee of the group may think desirable." He said that at the time of year when the Annual Meeting of the Association was being held the spa practitioners were at their busiest. They suggested they should, if possible, be allowed to hold their annual meeting at the same time as the Balneological Section of the Royal Society of Medicine or the International Society of Medical Hydrology. These societies met in October, November, January, and March in London. Provincial meetings were held in April or May. What he had said applied to Buxton and York, and in a less degree to Bath. The Council would always have the power of veto.

Dr MACKENZIE agreed to the insertion of the words proposed with the addition of 'with the approval of the Council' and the meeting concurred.

Dr MINDELTON MARTIN (Gloucestershire) opposed the formation of groups within the Association. There were disadvantages in distinguishing the branches or the profession to which members of the British Medical Association belonged. There were representative bodies for the different branches, and there were not sufficient grounds for the formation of groups. The Chairman of the Organization Committee gave the impression that applications for the formation of groups would be so numerous that they would have to be referred to the Council, not to the Representative Body. If that were so, the proposal would seem to be more unfortunate than was thought. The question of forming groups should have been left to the Representative Body. (Applause)

Dr R G GOLDOY (Bath) said he was asked by the Spa Practitioners' Association to support the motion of the Chairman of the Organization Committee. When it was first suggested to form a Spa Practitioners' Association it was thought by many that the work of looking after their interests in view of the proposed extension of insurance benefits to cover rheumatic diseases and their treatment in the spas could be done by the British Medical Association, but it was found that the only spas directly represented in the Representative Body as Divisions were Bath and Harrogate, and they were by no means the only spas involved. Members practising in many of the smaller spas formed so small a minority that they could hardly hope to make their views heard even in their local Divisions, or to have their case taken up at the Representative Meeting. Still, many of them felt the proposal should not be proceeded with unless it was somehow under the aegis of the British Medical Association, they felt that the Association was the right body to deal with any possible medico-political contingencies that might arise. It was only after the officials of the Spa Federation approached the British Medical Association and had an interview with Sir Robert Bolam and Dr Cox—who assured them that the Association was receptive to the formation of a Spa Practitioners' Association and hoped eventually to bring it under its wing—that they agreed to its formation. It was impossible for them to get their views heard through the ordinary machinery of the British Medical Association and he therefore suggested that the formation of groups for special purposes should be considered favourably. It rested with the Council to determine what the special purposes were, they might be permanent or temporary, but it was very desirable the Association should keep within its own hands all medico-political questions that were exercising the profession.

Mr PRINCE HARMAN, speaking not as an officer of the Association but as a member of a group, supported the motion. Three or four years ago it was found to be exceedingly difficult to collect the views of ophthalmic surgeons on certain matters, and one or two of the members in the Metropolitan Counties area asked him how they could collect their views and express them through the Association. In effort to get together a small committee in the Branch not succeeding, some young ophthalmic surgeons banded themselves together and made an association outside the British Medical Association to bring pressure to bear upon the authorities upon a medico-political affair which the Association should be foremost in advancing. That was what happened when existing arrangements were not sufficiently elastic to meet the group needs of the time. Therefore he wholeheartedly commended the proposal before the meeting. Although not a pathologist he had considerable connexion with pathologists and heard from them of the difficulties they met with as ophthalmic surgeons. If the rules and arrangements of the British Medical Association were expanded in the way proposed they would be able to meet difficulties as they arose and it would not in any way interfere with their general organization.

Dr DAVID CROW (Gloucestershire) said that although his Branch had instructed him to vote against the resolution, he felt there ought to be some sort of liaison

between the Association and the new medical bodies that were coming into existence. At all costs the essential unity of the Association should be preserved. It would be rather unfortunate if the new scheme were successful and a large number of groups were formed within the Association, because the various questions that arose should be looked at from the broadest point of view. The new bodies that were coming into existence were not formed for scientific purposes, but for medico-political purposes, and a small group of that kind would not be of much use without the support of the Association. The experience of the Medical Officers of Health Association brought out very clearly that in any difficulties they had they looked to, and depended upon the support of the Association. He did not think it was desirable actually to form groups or to lay down the machinery by which they could be brought into existence. Another objection was that it might lead to a considerable addition to the Association's expenses.

The CHAIRMAN of Council said that his name had been imported into the matter quite in error as agreeing to the formation of a Spa Practitioners' Association. The Treasurer had suggested that a large body of men like ophthalmic surgeons would be eligible, under such a mechanism to form a special group. If members would look at Appendix III Paragraph 2, they would see that it was not suggested that large bodies were the people for whom the mechanism was specially designed. The Council believed that the scheme would meet the needs of people who were scattered and few in number and perhaps only to be found in certain areas. He had a great deal of sympathy with the Gloucestershire resolution. All sections of the profession should take a hand in the Divisional meetings and should not feel that their particular needs were met quite adequately in some special group meetings. He quite saw that there was need in some few cases for the mechanism suggested.

Dr MONTAGUE MACKENZIE said that he was convinced that there was need for some organization of the kind to meet special circumstances which did not arise very often, but arose urgently when they did arise.

Dr MINDELTON MARTIN moved as an amendment that the matter be referred back to the Council.

The amendment was negatived.

The motion was then carried, with the proviso that the amendments which had been proposed on behalf of the Harrogate Branch should be taken into consideration by the Council.

#### Other Organization Matters

Dr MONTAGUE MACKENZIE moved that the remainder of the Annual Report of Council under "Organization" be approved. In doing so he said that he was happy to state that the total membership had increased by the splendid figure of 1800 in the past year. During the last four years it had increased by over 8000 or more than 30 per cent. Of the 1800 new members it was interesting to see that no fewer than 700 came from overseas. The actual number of new members elected was 2,800. Of the 1100 who had been in arrears no fewer than 814 or 73 per cent had been coaxed by the excellent finance department into paying their arrears. There was gratifying evidence of great activity in the Divisions and the Branches more particularly on the scientific side. With regard to last year's resolution which was proposed by the Brighton Division as to the holding locally of conferences with allied societies the Council was quite sympathetic to the proposal but it felt that it would be better to consider each suggestion on its merits rather than draft a general scheme for such conferences. Small conferences might dissipate the energies of the Association, and also its finances and might take away some of the splendour of the great Annual Meeting. If an allied society happened to be holding a meeting in a town, a town perhaps not quite so large as the towns in which the Annual Meetings of the Association were held, the Council thought that there would be every advantage in the local Branch or Division co-operating as far as its ordinary funds allowed and in very special circumstances the Council would be prepared to consider an application for a supplementary grant.

He had a very satisfactory report to make with regard to the overseas Branches. South Africa's new constitution appeared to be working well. The organization had been incorporated under South African law. The Federal Council had applied itself with great energy to the amalgamation of the medical journals in South Africa and to the provision of an Organizing Secretary. The financial help of the Association in London had enabled it to carry out both those objects. He was sure that members in this country could congratulate their South African colleagues on their progress, and especially on the fact that they had found that all they wanted could be achieved as part of the great medical association of the Empire as a whole. Australia went its very efficient way with a very good figure of membership. Queensland had incorporated itself. The Association in this country kept closely in touch with all the overseas Branches. There were now fifty such Branches.

As to the central activities of the Organization Committee, the great event centrally had been the lecture which Sir Berkeley Moynihan gave last autumn on "Cancer and how to fight it." Experience had shown that such a lecture given by a first-class lecturer in the Association's own Hall, with a kind press, was a very great factor in convincing the public that the Association had the common health at heart, and it could not fail to do the Association great good. The ordinary activities of the Association had been carried on as usual. New Divisions had been formed wherever the need had arisen. Very excellent recruiting work had been done among the newly qualified men. He would like to mention specially Dr Farquhar Murray of Newcastle, Dr Matthews of Liverpool, Dr Barnes of Sheffield, and Dr Storey of Belfast. Glasgow had done exceptionally good work. He had watched its recruiting figures with great interest. They had frequently been over 90 per cent, and even 95 per cent. At the May qualification in Glasgow 100 per cent of the men who qualified joined the Association. (Applause.) In that connexion he would like to mention the work of Dr G. A. Allan and Dr J. G. McCutcheon. Lastly, the *Handbook for Recently Qualified Medical Practitioners* had been of increasing use. It was most valuable as showing the pitfalls to be avoided and the lines to be adopted.

Dr F. C. MANTLEY congratulated Dr Morton Mackenzie on the numerous good points in his speech, but wished to draw attention to some unfortunate things that had occurred. He referred to the membership figures. Dr Mackenzie had rightly emphasized the fact that the membership was increasing, but he had not emphasized that the resignations also had increased. Some unfortunate cases of resignation had come before him (the speaker's) notice. One case was that of a gentleman who was lecturer on bacteriology in the provinces. For three years he had paid to the Association a subscription of two guineas. Last year he came to London on a whole-time research job. He had been informed that he was not eligible at the two guineas rate. He naturally protested. His claim was, "I am a whole-time research worker," and he was told, "No, you are not." No inquiries had been made of him personally. Another case, a similar one, had come to him (Dr Mantley's) notice. There were other men who were doing whole-time research work who had received notice that they must pay three guineas. They were not going to pay it, and they were simply going out. It seemed to him that the Organization Committee was going outside its powers when there was in existence a definite by-law which laid it down that whole-time research workers could be members for a subscription of two guineas.

Dr Morton Mackenzie said that as Dr Mantley had not given the names of the gentlemen concerned he could not make a specific answer to those cases, but the procedure was that all such cases came before the Organization Committee, which then deputed him to deal with them, and afterwards to report back what action he had taken. The Organization Committee then approved or disapproved of his action. They were most difficult cases to deal with. The by-law itself was not very clear, but the way in which he had interpreted it (and the way in which he thought the Organization Committee would wish him to interpret it) had been that if a man was, as his life's

work, engaged in research work he should pay the smaller subscription, but that if a man—and there were many such men—was merely taking up a whole-time research job as part of his training and not as a life work, he was not entitled to the reduced subscription. He agreed that the whole question was in a most unsatisfactory position—so unsatisfactory that the Organization Committee was seriously considering whether the by-law should not be abolished altogether, as it was giving so much trouble and causing so much ill feeling among members. The number of resignations was increasing, but not as rapidly as the number of new members. With an increased membership a slightly increased number of resignations must be expected. The resignations remained proportionately about the same each year. The reasons given for resignations were very often self-contradictory. One man writes resigning because he says the Association is doing too much for insurance practitioners, another man resigns because the Association is not doing enough for insurance practitioners and devotes the whole of its energies to non-insurance practitioners. Many of the reasons given for resignations were not in accordance with the facts, and were unfounded. On the whole the number of resignations received did not disturb him.

The motion was adopted.

Dr Morton Mackenzie then moved that the Supplementary Report of the Council under "Organization" be approved. It contained, he said, the names of the retiring secretaries, to whom the Association was extremely grateful. In making his remarks about the work in the Divisions, he had omitted to say how much the Council and the Organization Committee felt gratitude to those officers of the Divisions who carried out the work at the periphery. A great deal of the Association's success depended on the Division secretaries, Division chairmen, and Branch secretaries and Branch chairmen, and he wished to express the Association's gratitude to them for their work.

The report also contained a list of the Divisions which had not yet passed the organization rules. He made a very special and earnest appeal to those Divisions, especially as they were so few in number, to pass the rules at the earliest possible moment.

The motion to adopt the Supplementary Report under this heading was carried.

Dr J. B. MILLER (Lancashire) moved to instruct the Council to take steps to secure that members attending meetings of Council and central committees were paid reasonable out-of-pocket expenses in addition to railway fares. He said his Division clearly recognized that there had been no difficulty in the past in obtaining the services of members of the very best type both on the Council and on the central committees, nor did they anticipate that there was likely to be any difficulty in the future, but it was clear that a member who had to proceed to headquarters and to leave his practice several times a year suffered to a certain extent pecuniarily, the loss possibly being in inverse proportion to the standard of medical ethics prevailing in the district in which he practised. (Laughter.) There were, of course, compensations, the provincial enjoyed a visit to London, he gathered with professional friends from all over the country, he saw new faces, he might possibly even meet with new ideas—(laughter)—and he returned home refreshed and stimulated mentally, if somewhat jaded bodily. The necessary outlay, however, was considerable. It was not proposed to return all expenses, those naturally varied with the ideas of the representative himself. His Division suggested as a basis a scale somewhat on the same lines as the costs allowed to civil servants. The amount varied with the number of hours of business, which seemed to be quite a sound basis for a scale of expenses. No new principle seemed to be involved in the matter. At present what were termed "light refreshments" were allowed at meetings of the Association. If tea be allowed at an afternoon meeting, why not luncheon for a whole day's meeting, and why not bed and breakfast for a meeting involving absence from home for the night? After quoting anomalies of the present system of payment of expenses, Dr Miller argued that the

additional cost involved would not be very great. In any case, his Division felt that the time had now come when the services of the members who so ungrudgingly gave their time to the general body of the Association in attending to committee work at headquarters ought to be recognized at least to the small extent of returning to them their out-of-pocket expenses.

Dr PETER MACDONALD (York) supported the motion, but thought it should not be mandatory on the Council, but rather referred to them for favourable consideration. He believed the time had come for the Council to consider the matter very earnestly. He agreed that probably the Association had not suffered much up to the present—in fact, the Association's work was being extraordinarily well done, but at the moment the Association was restricted in its choice of the people who were going to do its work by the very worst form of restriction possible—namely, the pockets of the people who were chosen, or who were willing to do it. He thought the extra cost would be more than the sum mentioned by Dr Miller, but there was no need for alarm in that respect, in any case the efficiency of the work of the Association was much more important than the added cost.

Dr MILLER accepted the suggestion that the matter should be referred to the Council for their consideration.

The CHAIRMAN said the motion now took the form "That the Council be instructed to consider the taking of such steps as are necessary to secure that members attending meetings of Council" etc.

The TREASURER pointed out that the draftsman of the motion seemed to have forgotten the chief organ of the Association—namely, the Representative Meeting. If the difficulties and hardships of members of Council and of the central committees were considered why should not the equal difficulties and hardships of the representatives attending the Representative Meeting also be considered? The motion could not be left as it was. In all fairness the words "and Representative Meetings" must be added, and when the matter was looked at from that point of view the cost to the Association would be very serious indeed. The cost of travelling and all legitimate expenses at present came to £5 000 or £6 000 a year. If the proposed additional expenses were added it would not mean a 20 per cent addition but more probably a 100 per cent addition. The finances of the Association could not bear that cost. It would mean crippling the work of the Association and doing away with the opportunities of members of working for the good of the profession. The difficulties of the situation had been met in the past by local effort and it was far better that they should continue to be so met than that the funds of the Association should be saddled with a cost which must be applied equally to all, whether they could afford it or not. The Treasurer added however that he had not the slightest objection to the motion going before the Council and being examined as similar motions had been before the Council about six times during the last fifteen years, though he thought the result would be the same as before.

Dr J. B. MILLER in reply said that there was no comparison between a Representative Meeting attended under the happiest conditions of season and surroundings, and a central committee meeting attended, perhaps in a November fog in London.

The motion was a reference to the Council it was carried, and the meeting adjourned for lunch.

### THE ASSOCIATION BUILDING

The building extensions at headquarters in Tavistock Square were considered as the first business after lunch the Representatives meeting for this purpose in the Anatomical Theatre where the proposed extensions could conveniently be demonstrated.

Sir ROBERT BOLAM (Chairman of the Building Committee) made a long statement on the position with regard to the building and his remarks were illustrated by lantern slides of photographs and plans of the present and proposed buildings. He also made a private statement with regard to the financial considerations attending the scheme. At the close he was accorded an ovation by the meeting.

Those who spoke in warm support of the scheme were Dr J. A. Macdonald, Dr W. Douglas, Dr C. H. Milburn, Mr Bishop Harman, Dr H. P. Frederick, Dr Milner Moore, Dr J. Dewart, Sir Llew. Maclean, Dr Christie Murrell (speaking for women who are a little more cautious financially), Mr W. L. Hempson (the new honorary member), and the Chairman (Dr Braclenbury). In response to an invitation by the Chairman to express any doubts or hesitations, Dr Middleton Martin and Dr David Lawson asked some questions, which were answered by Sir Robert Bolam.

At the close the motion that the report of Council under "Building" be approved was carried certainly without dissent, and apparently unanimously, with loud acclamation.

### "BRITISH MEDICAL JOURNAL"

When the Representative Body resumed its public session,

Dr J. A. MACDONALD (Chairman of the Journal Committee) moved approval of the Report of the Council under "British Medical Journal." He said the Journal was maintaining and strengthening its pre-eminent position as the first journal connected with the profession. The literary portion of the Journal maintained its high standard, the articles the special communications from distinguished men the epitome of foreign medical literature, etc. were quite as good as and possibly better than ever. The Association was to be congratulated on having an editorial staff that showed such taste and discrimination and journalistic flair for what was best for such a publication. In the matter of advertisements it continued to progress in the most extraordinary manner. In 1914 the income from advertisements was only about half what it was now though the number of pages of advertisements then was much greater than now. This was largely due to the way in which the business had been handled by Mr Ferris-Scott. The question of advertisements was one of the most difficult with which the Journal Committee had to do. They sought to allow nothing to appear in the advertisement pages that was incompatible with the position held by the Journal in the medical world. They did not guarantee that the matters and preparations advertised in the Journal could be absolutely relied on for all that was said of them but through a process of careful sifting they allowed very few things to appear in the advertisement pages or the Journal for which they could not stand. The greatest care was exercised at every stage and he did not think more could be done to keep the advertisement pages free from anything objectionable. From advertisements the revenue in 1926 was £45 000. It would be seen how great a asset that was to the income of the Association.

Dr L. A. PARRY (Brighton) moved

That whilst recognizing the responsibility for all that appears in the British Medical Journal and its Supplement as defined in Article 33 of the Association the Representative Body is of opinion that these periodicals should be open to communications from any member commenting favourably or otherwise either on the policy of the Association in regard to the medical and allied sciences, or on a communication inserted by a department of the Association.

Dr PARRY emphasized that this was not a personal matter but one of principle. The resolution had the unanimous support of the Brighton Division. The admiration he had for the Journal's editorial staff and committee was lost when he regarded them in their corporate capacity. In the Journal of February 26th appeared a leading article two leaderettes and two reports of meetings on a certain subject. He wrote to the Editor differing from the opinions expressed in those two articles. His letter was refused publication on the one ground that he held different views from those of one committee. He asked the Editor to submit the matter to the Journal Committee and he asked the committee a specific question. They supported the Editor, and did not reply to his question whether it was a principle or practice of the Association to refuse to allow both sides of controversial questions to be discussed in the Journal and if not, why was his letter refused publication? He

had had no answer to that query, though he had received an answer to another question that he did not ask and which did not interest him. The report of the Journal Committee was submitted to the Council, which, without seeing his letters, approved its action. The *JOURNAL* differed from other periodicals, in that it was not a political organ and belonged to the members of the Association. They had a perfect right to express their views on any medical or allied subject discussed in the *JOURNAL*. To allow only one side to appear was a suppression of freedom of thought. The letter of another member of the Brighton Division was refused publication on the ground that discussion of the subject to which it referred was closed. He knew of other similar cases. The medical profession was often wrongly accused of being bigoted and intolerant, but the Journal Committee, supported by the Council, had definitely refused to permit medical matters on which it was legitimate to hold diverse opinions to be discussed in the *JOURNAL*. The only reason he could suggest for this was that the Council wanted it to be thought that on certain subjects the profession was unanimous, when it was far from being so. The principle at stake was whether the Journal Committee, supported by the Council, had the right, having made up their minds on certain subjects, to refuse the 32,000 members of the Association the right of expressing diverse views.

Dr C O HAWTHORNE advised the Representative Meeting to give no countenance to the Brighton proposal. He fully accepted Dr Parry's assurance that he was not animated by personal motives. He had admitted that the principle at stake was whether it would be possible to obtain a capable editor if one of the conditions of his position was that each of the 32,000 members of the Association had a right for any letter he wrote on a matter engaging the attention of the Association to appear in the *JOURNAL*. Article 38 of the Association put upon the Editor responsibility for what appeared in the *JOURNAL*, not, as Brighton's motion implied, upon the Representative Body. Brighton wished to take this responsibility away from the Editor, and to bind him to insert a letter of communication from any one of the 32,000 members. That would produce a condition of chaos, and no capable editor would accept such a position. An editor must be either trusted or dismissed. Responsibility and authority went together. On certain occasions the Editor had done him, as Chairman of the Science Committee, the honour of asking his opinion, and each time it seemed to him—if it were not impertinence to praise the Editor—he had shown anxiety that to him seemed excessive, and on such matters he regarded him as exercising a degree of charity that he would find it difficult to compass. The rank of the *BRITISH MEDICAL JOURNAL* was second to none, and it was evidence of its value that £6,000 was paid for copies by non-members of the Association. Responsibility and authority could not be divorced, and he asked the meeting to vote against the motion.

Dr J A MACDONALD said that there were several inaccuracies in Dr Parry's speech. One of the statements in it was that the idea seemed to be that a man might not criticize the action of one of the committees. The action which had been taken was not the action of one of the committees, it was the action of the Council itself. The Council had given instructions to the Science Committee to carry out a strong propaganda. That was the question discussed at the time by the Journal Committee. Dr Parry had stated that the Journal Committee was the body that refused the insertion of the communication in the *JOURNAL*, but the committee really had nothing to do with it except that it was asked afterwards to express its opinion as to whether it approved or disapproved of the action taken. But, in fact, the only body to which the Editor was responsible was the Council. Every single letter that was refused was considered by the Editor in view of the circumstances existing at the time, and it was the Editor alone who decided whether or not a letter was suitable for insertion in the *JOURNAL* on any particular occasion.

The CHAIRMAN OF COUNCIL did not think that anybody would quarrel with the resolution as it was framed, but he thought that the Representative Body as a whole would

disagree with the interpretation which Dr Parry asked it to accept. The columns of the *JOURNAL* were open not only to members of the Association, but to anybody outside, subject always to the discretion of the Editor. There were only two exceptions to that statement. One was that the *JOURNAL* should publish certain official announcements, regulations, and by-laws, and alterations therein, from time to time. The other was that if the Editor was instructed by the Council to put something into the *JOURNAL* he must do so. With those two exceptions the Editor was free to exercise his ability and his discretion. No important journal could be conducted on other lines. The *JOURNAL* was a medical journal for the medical profession. It held, in open competition, the premier place in Great Britain. It was one of the most important journals in the world. It had climbed that pinnacle largely by the eminence and the discretion of its present Editor (Applause). The Editor had made one mistake, and that was in endeavouring to give any reason why he refused anybody's letter. There was no need for him to give any reason. There was no need for the Journal Committee to be imported into the matter. It was not possible to have an official valued and respected as Sir Dawson Williams was, hampered by being compelled to allow any member of the Association to have anything that he wished inserted. Imagine what would be the size of the weekly issue! Consider the amount of mutual, scientific and controversial, that was omitted every week. The proposition was impossible and intolerable. He could quite imagine that Dr Parry felt that he had views which he thought it would have been well to put before the profession at the particular moment, but he knew Dr Parry well enough to believe that he would see quite clearly that it would be impossible to conduct a scientific journal on lines such as those he proposed to lay down in his interpretation of the resolution. He hoped that, having ventilated the subject, Dr Parry would see that he might gracefully withdraw his resolution.

Dr Parry said that he had been credited with saying many things that he had not said. Dr Hawthorne had suggested that he had laid it down as a principle that any one of the 32,000 members of the Association should have the right to have a letter inserted in the *JOURNAL* if he wished to do so. He had made no such suggestion. The suggestion he had made was that, a controversial subject having been referred to over and over again in the *JOURNAL*, the other side ought to be heard. That was the only principle that he had laid down. Every fair-minded man must see that it was impossible to get the opinion of the profession unless both sides were represented. He had not attacked the *JOURNAL*. He had not said that it was not one of the best and finest journals in the world. He could not withdraw the resolution, and he must ask for it to be put to the vote. He had made no attack on the Editor. He had the greatest respect and admiration for the editorial staff and for the way in which the *JOURNAL* was conducted.

The motion was negatived by an overwhelming majority, only two or three hands being held up in its favour.

#### Reports of Division and Branch Meetings

The CHAIRMAN, on behalf of the Plymouth representative, who was absent, moved that the reports of Division and Branch meetings should be more extensive and in larger type.

Dr MACDONALD said he hoped the motion would not be passed. The question was whether it was better to disturb the balance of the *JOURNAL* by inserting local matter at greater length and more prominently, or to carry on as at present and make matters of general interest the more important part of the *JOURNAL*.

The motion was lost.

#### PROCEEDINGS OF ANNUAL MEETING

Dr J STEVENS (Edinburgh and Leith) desired to instruct the Council to consider the question of publishing the proceedings of the Annual Meeting in one volume as soon as possible after the meeting, and of making, if necessary, extra charge for the publication. His reasons for doing so,

he said were, first that the appearance of the proceedings had led but in the *JOURNAL* which led to considerable delay in their complete publication, secondly, that owing to the long continuance of such publication the work was blocked to a considerable extent for other matter appearing in the *JOURNAL* during that time, and thirdly, that the course he suggested would be of much more value to the members, and would enable them the better to peruse the transactions.

Mr McLEOD ECCLES inquired whether Dr Stevens meant that the proceedings of the Annual Meeting should be published in a separate volume, and that 35,000 copies of that volume should be sent out, one to every member of the Association. Dr STEVENS replied that that would be a point for the Council to consider.

Dr J. A. McDOUGALL pointed out that the proposal had been considered twice before, in 1896 and in 1908, and on both occasions it had been rejected. A plan of the kind had been tried in connexion with the publication of the proceedings of the special scientific and clinical meeting held in 1919, but the result had not been encouraging. That particular volume had cost £395 to produce; it had been published at the price of 2s., and there had been no sale for it. At the present time, owing to the increased price of paper, overhead charges, etc., a similar publication would cost a very large sum, and he did not think many copies would be sold. Moreover, many papers of great value and interest were contributed to the Sections at the Annual Meetings, and their publication was an advantage to the *JOURNAL* and its readers.

The motion was lost.

#### *Illustrations in the Journal*

Dr STEVENS (Edinburgh and Leith) asked the Council to consider the possibility of improving the general quality of the illustrations. He thought it would be well worth the extra expense involved.

Dr McDOUGALL said the matter had been carefully considered by the Journal Committee and by the Council. After briefly explaining the different modes of reproduction and the difficulty of getting good results on ordinary paper by rapid printing on rotary presses from stereotypes, he stated that the *JOURNAL* was now publishing certain special plates which he thought, were highly creditable to the *JOURNAL* and satisfactory to the members. The cost involved in a more extensive publication of art paper supplements was almost prohibitive. Those in charge of the *JOURNAL* would gladly move in the matter if the Finance Committee could be persuaded to give permission for the money to be spent. He drew attention to the excellence of many of the illustrations now appearing in the *JOURNAL*, especially the coloured portrait of Lord Lister which was appearing in the current number. The Council did not require any urging to do its best in the matter, but the governing consideration was the cost.

The resolution was withdrawn.

### MEDICAL ETHICS

#### *Advertisements of Therapeutic Institutions*

Dr A. LINDON (Chairman of the Ethical Committee) moved on behalf of the Council.

That the Representative Body considers it undesirable that there should be inserted in the medical press or in other publications primarily intended for the medical profession any advertisement of a therapeutic institution which includes any laudatory statement of the form of treatment given, or the private address or the consulting rooms or hours of a member of the medical staff, but that there is no objection to the name and qualifications of medical officers of the institution being given.

In doing so, he said it might be well if he told the representatives the reasons which had actuated the Council in putting forward the motion. In 1924 the Representative Body had passed a resolution relating to the advertisements of institutions professing to provide medical advice and treatment, and it had stated that the practice was free from objection and that such advertisements might include the names of the resident and visiting medical officers. It had been found as a matter of experience by the Council that from week to week advertisements of

those institutions had appeared in the *JOURNAL*, which were open to certain objections. They were open to the objection that they contained laudatory statements of the form of treatment given, and the private addresses of the medical officers, the addresses of their consulting rooms and the hours at which they could be consulted—very often in a different part of England from that in which the institution advertised was situated—and the Council had come to the conclusion that it was undesirable that those statements should be allowed in the *JOURNAL*. Therefore, on behalf of the Council, he moved the resolution.

Dr F. RUDOLPH (Council) said that the resolution was one which had caused him considerable anxiety because the *JOURNAL* had for a long period regularly accepted an advertisement which would be forbidden by the resolution as at present worded. That advertisement stated that there was a certain asylum in existence and that the medical superintendent could be seen at his consulting rooms in such and such a place at which he would interview friends and doctors of patients. He did not want to alter the resolution in such a way that a doctor would be able to take advantage of his professional colleagues, but he would like to see it altered in such a way that the asylum to which he had referred would be able to advertise as it had been advertising hitherto. He moved that the latter part of the resolution should read as follows: "advertisement of a therapeutic institution which includes any laudatory statement of the form of treatment given, or information giving the private address or the consulting rooms or hours of a member of the medical staff which is in any way calculated to promote his private interests, but that there is no objection to the name and qualifications of medical officers of the institution being given." Those words would carry out what Dr Lindon had suggested and would allow a very worthy institution which was valued very much to continue as it had been going on, and it would not be said that what it had done was contrary to anyone's professional interests.

The amendment was seconded by Dr J. D. Ewart.

Mr McLEOD ECCLES (Council) could not see that the amendment really covered the question which members were anxious it should cover. In the previous issue of the *JOURNAL* it would be found that there were no fewer than six advertisements all in connexion with mental disease, in which the actual address of the doctor at his consulting room was totally different from the institution in which he was working.

The CHAIRMAN OF COUNCIL thought that Dr Rudolph's proposal would put upon the office work which would be very difficult and responsible. It would put upon the secretariat a duty which the General Medical Council found it very difficult to discharge in somewhat similar cases. He thought that it would be very ill advised to do that. He imagined that some other form of words might be found which would cover an obviously desirable exception such as that which had been mentioned, but he was perfectly certain that the suggested words would not do that. They would only open the door to fresh difficulties.

After some discussion and consultation.

The CHAIRMAN said that Dr Rudolph had asked him to move the amendment in another form. The words would be as follows: "or the address or the consulting rooms or the hours of a member of the consulting staff at which he sees private patients."

Dr J. D. Ewart as seconder stated that he was prepared to second the amendment in its altered form. The meeting gave leave to the mover and seconder to alter the wording of the amendment.

Dr LINDON said that he was willing to accept the amendment as now proposed.

Dr KARWIA (Bombay) objected to the words "but that there is no objection to the name and qualifications of medical officers of the institution being given." In his opinion those words should be omitted. In Bombay the medical men had decided that the very fact that the name and address of the doctors serving in an institution in any capacity were mentioned gave a sort of advertisement to the persons who were so named. It was the duty of every medical man to raise the standard of medical ethics as much as possible, and never to take a retrograde step by publicly

advertising, either directly or indirectly. He hoped that the resolution would be passed as intended, but with the omission of the words to which he was now objecting. If the name and address of any particular man connected with an institution were advertised the men who were not connected with such institutions were placed in a position of disadvantage. Only merit and qualifications should decide the prestige and earnings of a man, not advertisement. If the words against which he was speaking were adopted, the result would be that many so-called institutions would crop up simply to advertise men who needed advertisement.

The CHAIRMAN pointed out that the omission of the phrase would not accomplish the aim of the mover of the amendment, a positive phrase must be inserted—"That it is objectionable that the name and qualifications of medical officers of the institutions should be given."

The amendment having been moved in that form, Dr ROXBOROUGH seconded it and complimented Dr KAPADIA on his excellent speech.

A REPRESENTATIVE asked whether the amendment was in order, it having been the policy of the Association since 1924 that the names of medical officers should be published in the BRITISH MEDICAL JOURNAL. The CHAIRMAN replied that the amendment was in order, because the proposition was that the time-honoured policy should be varied.

The REPRESENTATIVE: But to do that is it not necessary to give two months' notice in the JOURNAL?

The CHAIRMAN: That part of this resolution would not be the policy of the Association in the technical sense, but an expression of opinion by the meeting.

Dr LONDON-DOWN asked if the mover of the resolution wished to preclude publication of particulars concerning medical men attached to institutions who were not in private practice. He did not think the Association should do that. The CHAIRMAN replied that the amendment is altered did that. The meeting had nothing to do with intentions, except in debate, only with words or propositions put before them.

Dr LONDON-DOWN, while admitting the high aim of the amendment, advised caution. It would bring about such a great and unconsidered change in the attitude as to cause consternation. In all ethical questions they had to consider what had been the agreed custom for a long time. In many places the names of medical staffs of public institutions were always regularly published, and that custom was held to be very desirable.

Dr LONDON was not prepared to accept the amendment, heartily endorsing what Dr LONDON-DOWN had said. The resolution applied not only to medical journals, but to other publications primarily intended for the profession. For many years it had been the custom for the institutions in question to be advertised in the *Medical Directory*, with the names and qualifications of the medical officers. That was quite free from any offence and had not led to personal advertisement.

Dr H G L HAYNES (Mid-Essex) asked, as many public hospitals, general and mental, took private patients, how could the names of part of the staff be excluded?

Dr KAPADIA said that a custom of many years' standing was no justification for continuance. He stressed the injustice to practitioners and consultants who were not in connexion with established institutions and had no opportunities to bring their names and qualifications before the public. His amendment would avoid that divisions distinction. In Bombay it had been agreed among medical men that in no circumstances should names and qualifications of doctors be advertised in any shape. If anyone wanted to know who was the conductor or medical man in charge of an institution the proper method was to write to the institution. What was proposed was a retrograde movement from the point of view of higher medical ethics, he wanted to raise the standard.

The amendment was lost and the original resolution carried.

Dr LONDON, in moving the approval of the remainder of the Annual Report under this heading, called attention to the paragraph in the Report of Council to the effect that they considered it unnecessary and undesirable for the

Association to prepare and issue an ethical code in view of the fact that some thirty pages of the *Handbook for Recently Qualified Medical Practitioners* dealt with the subject.

The report was agreed to.

#### Newly Qualified Practitioners and Medical Ethics

Dr C H MILBURN (Harrowgate) moved to instruct the Council to consider any further steps which might be thought necessary for the instruction of senior students or newly qualified practitioners in medical ethics. He referred to the growth of the habit of writing to the lay press, letters on all subjects, whether medical or not. The practice seemed to be common in all classes of the profession, from the newly qualified to the ranks of knights and baronets. Such letters might have beneficial effects, but in many of them reflected the confused mentality of the writers as to the objects, powers, and responsibilities respectively of the British Medical Association and the General Medical Council. That had been very evident in some of the letters he had read from men who in the past had been looked up to in some respects as trusted leaders of the profession. A few years ago an effort was made by the Chairman of Council to restrict the tendency, but that seemed to him to be beginning at the wrong end, and he thought it desirable that senior students or newly qualified men should have the opportunity of being instructed in medical ethics. Without trenching on the powers and responsibilities of the General Medical Council, there was no reason why the Association should not apply in the proper quarters pressure for giving incoming members of the profession thorough instruction in medical ethics, and so do away to a large extent with the necessity for disciplinary action.

Dr J F WALKER (Southend) said the matter was even more important than the proposer of the resolution seemed to think. The non-observance of common ethical principles had far-reaching effects. For instance, the delicate question of succession produced an enormous amount of irritation between colleagues. The unedifying spectacle of quarrels between medical men lowered the profession in the eyes of the public. Dr Walker added that although instruction was now given to students in almost every branch of medicine, yet on this important matter there was no definite attempt whatever to give instruction. The best remedy would be for every batch of newly qualified men to have a talk from a general practitioner of many years' experience. Practically the only thing one was told on the momentous night of qualification was that one's horses could not be taken for fire engines, and one would not have to serve on a jury!

Sir ROBERT BORLASE thought there was no harm in passing the resolution, but he would not like the Representative Body to feel that nothing was being done systematically to inculcate in the medical schools the principles of ethics, both by the example of teachers and also by systematic lectures. The General Medical Council, in its investigation of the curriculum, had had reports from the various teaching institutions, and there seemed every evidence that care was now being taken in this type of instruction, and that the authorities of the schools were aware of the need. Still, there was no harm in asking the Council to be vigilant in order that this type of instruction might rather increase than diminish.

Dr LONDON said that the General Medical Council it off took action as long ago as 1922, when it passed a resolution, which was sent to all the universities and medical schools, stating that instruction should be given in the courses of forensic medicine and public health or otherwise on the duties which devolved upon practitioners in their relations to the State and on the generally recognized rules of medical ethics. That notice had been carried out, he believed, by all the universities and by a large number of the medical schools. At one of the medical schools in London, the lectures on public health gave at least three lectures on medical ethics every term, and the surgeons and physicians also took every opportunity, when going round the wards with the students, to impress upon them the

Importance of the subject. There were all anxious that anything which could be done to improve the instruction in medical ethics should be done.

The motion was carried.

### Professional Disputes

Dr LYDON then moved as a recommendation of Council

That having reviewed the existing machinery of the Association regarding ethical matters the Representative Body is of opinion that no extension of that machinery is at present necessary or desirable.

He said that the Council had been asked by the Council of the Metropolitan Counties Branch to consider the present machinery for dealing with professional disputes and as a result an appendix to the Supplementary Report would be found dealing with the procedure at present followed and certain suggestions for possible developments, but the Council was of the opinion stated in the recommendation. He appealed to the Divisions, twelve in number, which had not yet adopted the ethical rules to do so without further delay because on several occasions it had very seriously prejudiced the interests of the members in those Divisions that the ethical machinery had not been able to function in the areas.

The motion was carried, and the remainder of this portion of the report was approved.

The meeting adjourned at 6.15 p.m.

Saturday July 16th

### THE CHAIRMAN

The chair was taken by Dr C. O. HAWTHORNE (Deputy Chairman) in the absence of Dr Brackenbury through illness. Sir ROBERT BOLAM announced that Dr Brackenbury who had been seized with temporary illness the previous evening was very much better and indeed had wished to resume his work, but he (Sir Robert Bolam) had persuaded him—indeed had ordered him—to remain in bed. Prof. or Willie had seen him and had stated that he might resume the chair on Monday morning.

As Dr Hawthorne in his capacity as Chairman of the Science Committee had to present the Report of the Council under "Science" the meeting elected on the proposition of the CHAIRMAN of COUNCIL Dr WALLACE HENRY to the chair during this part of the proceedings.

### SCIENCE

#### Pathological Institutes

Dr C. O. HAWTHORNE (Chairman of Science Committee) moved as a recommendation of Council

That the Representative Body disapprove of the establishment by trading firms of laboratories as subsidiary enterprises for the purpose of offering pathological examinations and reports on individual cases and advises members of the Association to avoid any association with such enterprises.

He said that this year there was imposed upon the usual report of the Science Committee a new section headed "Pathology". The Council at various times had received complaints from practitioners engaged in practice as private pathologists that their position was unfairly treated in two respects. First, advertisements of organizations were permitted in the medical journals whereas the private personal efforts of individuals were, in accordance with usual professional custom excluded and secondly there were certain commercial activities which came into competition with the reasonable and ethical standards governing the action of private members of the profession. That position was set forth at length in the Annual Report of Council (SEPTUAGINT April 23rd 1927). It was a matter of common knowledge that certain trading firms who had goods to supply to the profession did conduct pathological laboratories which it was not unfair to say were not motivated by a love of science or research, but by commercial and advertising ambitions, and the Council now wished to put it to the Representative Meeting that that was the type of ambition which the British Medical Association should discourage and it came to that conclusion upon two grounds. First, that this was unfair competition with the

private pathologist, and, secondly, if it was admitted to be a legitimate and proper thing for a commercial firm to cultivate a clinical laboratory and to give reports on specimens obtained from individual patients there was no reason why that class of undertaking should not be extended. One could imagine an enterprising firm setting up, as a subdepartment for advertising purposes an x-ray examination scheme and probably at low fees where there would be both unfair competition and, as they thought, undignified competition. Other and more undesirable extensions were conceivable.

This was agreed to without discussion.

### Pathological Reports

Dr HAWTHORNE further moved

That in the opinion of the Representative Body all institutions undertaking pathological examinations and reports should include in any intimation made for the profession the name of the registered medical practitioner in charge of the laboratory and that each report issued from the laboratory should be guaranteed by the personal signature in writing either of the practitioner or of some other registered medical practitioner approved by him.

Dr Hawthorne said the motion emphasized the character and the possibility of clinical pathological reports made in the investigation of individual cases.

The motion was agreed to.

Dr HAWTHORNE next moved

That in the opinion of the Representative Body public health authorities should neither provide for pathological examinations nor furnish pathological reports on individual cases except (1) in cases which directly involve question of public health or (2) where provision is made for such reports by statutory right or (3) when the patient is stated by the practitioner to be in his opinion unable to pay a fee.

Dr Hawthorne said that the motion recognized that there was a legitimate field for municipal or other public laboratories and that their responsibility extended to the investigation of specimens collected from individual patients. Further, the statutory right of individuals to receive pathological reports should not be interfered with. The intention was to guard the private interest of individual practitioners and to protect them against possible abuse also to secure municipal or public authorities from abuse by persons who could pay but tried to avoid payment.

Dr L. A. PARRY (Brighton) moved to leave out the third of these exceptions—namely when the patient is stated by the practitioner to be in his opinion unable to pay a fee. He said that to agree that a public authority should begin investigating pathological conditions was to put it into competition with the private practitioner. Any individual not able to pay for pathological examination could always get it done in hospital.

Dr HAWTHORNE said he would admit the validity of Dr PARRY'S contention if there were accessible private pathologists and hospitals in all parts of the country but notoriously there were not. He did not see how the profession could consistently take up an absolutely restrictive attitude toward examinations made by public authorities. Time was an essential element and the Association should not take up an attitude that implied that public health authorities in no circumstances should give results of examinations collected from private patients.

Dr C. F. S. LEXELL said that if the Science Committee's motion was passed wherever there was a public pathological authority it would be necessary to set up another laboratory in each area because as Dr Hawthorne had said it was important that in point of time the laboratories should be within easy reach of every practitioner. Instead of there being one large well equipped laboratory there would have to be two which could not be equipped as economically as one. In neither would the man in charge have the large and varied experience which was needed. Where a large amount of work was done smaller fees could be charged and was important from the point of view of the medical practitioner, who often hesitated to refer private patients to have pathological investigations carried out because of the expense. Two institutions involved the employment of two men, and the amount of money available for salary

had thus to be divided. It was much more important to have one institution with a well paid man. Work was not being taken away from private pathological practitioners. It had to be remembered that the greater part of the work was new work, and work which was due to the activities of the public health authorities. Had it not been for the latter, a large amount of the work would never have been done. It had also to be remembered that the large demand which now existed for pathologists, and the consequent supply, was largely due to the activities of the public health authorities in the matter. Medicine generally owed a very considerable debt to the Ministry of Health and to the public health bodies for the facilities they had given. The point could best be met, not by restricting the work they did, but by an active and sympathetic co-operation with them, while at the same time supporting the pathologists.

Dr CLARK TROTTER (Council), in support of the motion, stated that some time ago he had consulted an official of the Ministry of Health in the matter. He found it was very commonly thought by the various practitioners that a local authority was bound to do pathological examinations. That was not the case. He had been told that it was entirely within his own discretion, as medical officer of health, to say whether he thought the examination of any particular specimen was in the interests of public health in the way of preventing the spread of disease in the borough, and it was on those lines that the examination was undertaken. He had even known swabs to be taken from cases as a sort of placebo for the patient. There was also a good deal of indiscriminate swabbing of contacts which was of no use at all, because the patients were not suffering from a disease and they could not be treated as diphtheria cases. In Islington he had very strictly limited the cases in which he did pathological examinations, and if he got half a dozen swabs from one doctor all at once from a family, he very closely inquired into the case before having the examinations done. He would rather spend the money on doing tests for pathogenicity. A great number of supposed diphtheria cases were "pseudo," and not pathogenic, and if one could prove that the supposed carrier was non-toxic one was doing good work and spending the money usefully. His main object in speaking was to point out that it was not the case, as many practitioners thought, that they had only to send in pathological specimens and that they were bound to be done. The control should be kept by the public authority, who should exercise a discretion. It was on those lines that he was strongly in support of the motion, because it stated that it should involve questions of public health, and that was exactly the attitude that the official at the Ministry had taken when he had consulted him on the matter—namely, that if it was considered it did not involve questions of public health and was going to be a useless sort of examination, the local authority was not to be bound to do it. Having obtained that decision, he had thought it as well to place it before the meeting.

Dr H. S. BEADLES (Council) thought Dr Clark Trotter's argument was exactly the argument which should have been brought forward in opposition to the motion. It was found generally that practitioners wanted to have the possibility of getting general work done. As Dr Flemming had pointed out, if it was desired to have all that work done, a large public laboratory was necessary. Very great difficulty would be experienced in a number of cases if the public laboratory was limited only to a few items. It was practically limited now to diphtheria, syphilis, typhoid, and tuberculosis. He was looking forward to the day when the public laboratory would be open to all cases. Personally he was very strongly against the resolution.

Dr J. STEVENS (Edinburgh) took exception to Dr Clark Trotter's remarks. Dr Trotter claimed the right of the medical officer of health, who had not seen the cases, to decide whether or not he should have examinations made of the swabs sent by medical practitioners, who had seen the cases, and who had treated them, and who knew the circumstances of the household. Personally he took exception to that point of view. With regard to Dr Trotter's remarks about the examination of contacts, he did not

know what the experience was elsewhere, but in Edinburgh practitioners were sometimes asked by the medical officer of health to take swabs from contacts in the case of poor children in houses where a case of diphtheria had occurred, and they did so. They were taken on the request of the medical officer of health as a rule, if not always, and not by the practitioners themselves.

Dr S. C. DIXIE (Wolverhampton) traversed the statement made that the increase in pathological work was entirely due to the activities of public health bodies. In the view of a number of speakers, pathology consisted entirely of the examination of diphtheria swabs and sputum for tuberculosis. As a matter of fact, pathology consisted in a great deal more than that, and for the proper pursuit of pathology one was coming to realize more and more the absolute necessity of bringing the pathologist into the closest possible contact with the patient. On that account he very strongly supported the motion. Mention had also been made of the advantages of having one large laboratory instead of two, presumably referring to "two" as a public health laboratory on the one hand and a private laboratory or a laboratory attached to a voluntary hospital on the other. There was no question that better work could be done in one large laboratory, but it was also obvious that the functions of a public health laboratory and the functions of a laboratory attached to a voluntary hospital were two entirely different matters. In the one case specimens had to be dealt with in bulk, in the other, individual specimens had to be dealt with in reference to the individual patient. In all districts there existed an opening for laboratories of both sorts. In most cases private practising pathologists were the pathologists of the voluntary hospitals. In a good many districts the voluntary hospitals had not sufficient funds to pay an adequate retainer fee to a man who could do their pathological work solely. On the other hand, if the voluntary hospitals allowed their pathologists to do private work in their hospital laboratories, then the pathologists could add sufficiently to their income to enable the hospitals to get good men to take their pathological posts. It was most necessary that every hospital should have attached to it a competent pathologist working in a properly equipped laboratory, where there could be the closest contact between patient and pathologist, and where consultations could take place between the pathologist and members, not only of the honorary staff, but also of the practitioners of the surrounding district. That particular type of thing could only be brought about in clinical laboratories attached to voluntary hospitals. The latter could not establish these laboratories unless they got a certain amount of private work coming in to them. That private work they could not get if it was all going to be taken by the public health authorities.

Dr E. W. G. MISTERVIN said what he had to say was only a contribution to knowledge of how things were being worked. In his own borough (Camberwell), there was a very peculiar arrangement, which, perhaps, under the present motion, was carrying matters out exactly according to the proposed policy. There was a large Poor Law hospital, practically a municipal hospital, with a very fully equipped pathological laboratory, and in which all the work for the hospital was done, but that laboratory was also the municipal laboratory, and all the work for the municipal authorities was done there too—an arrangement which was very admirable. Although there were voluntary hospitals in the neighbourhood, they could not possibly undertake the work needed. The last speaker had intimated that it was only in voluntary hospitals that such kind of pathological work could be done. That was quite incorrect. His arrangements which his own borough had were now being made in many of the Poor Law hospitals in London. In addition to that, then, pathologist had his own laboratory with his own assistants, and there he dealt with the private work such as that described. That was a very good example of the carrying out of the policy proposed, but he had to confess that he was not at all satisfied that it was not a very roundabout and cumbrous method of doing things. He joined with Dr Flemming in the opinion that it would be far better for public authorities in many circumstances to allow their pathologists to carry

out the work of private practitioners under a private arrangement.

Mr H S SOUTTAR (Council) had the greatest possible sympathy with the proposition before the meeting but at the same time he quite saw the difficulty of the proposition in general who had only the public laboratory to fall back upon. He therefore proposed an amendment that after the words "That in the opinion of the Representative Body" there should be inserted "wherever other pathological facilities are available." Those words would cover both cases—where the pathologist was working privately, and where he was working in conjunction with a hospital. It seemed to him that they would provide a way of escape from the dilemma.

Dr FLEMING hoped that this amendment would not be accepted. The practitioner might be placed in the dilemma that there was a private laboratory with the work of which he was not satisfied. In that case he would be in an extraordinarily awkward position. The amendment might perhaps be worded differently.

The CHAIRMAN OF COUNCIL thought that Mr Souttar had not appreciated exactly what the full effect of his amendment would be. At the moment the situation that was being dealt with was anything but clarified. It might well be that it would develop so that there would be a new set of consultants, the pathologists. It might, on the other hand, be better for the community that that section of the profession should develop, aided by public health authorities and hospitals. In a short time the national health insurance scheme would undoubtedly take a hand in the work and conditions would be laid down. In the meantime it would be well to leave the whole situation fluid. Therein lay safety in the other way lay danger.

Dr HAWTHORNE said that there were two reasons why he felt unable on behalf of the Council to accept the amendment. The first was that if it was adopted it would be necessary to find some proper authority if he might put it so which would be prepared in every individual case to say when other facilities were or were not available. The second reason was that it challenged the right of public health authorities to have laboratories for any examinations even for examinations made admittedly in the interests of the public health.

Mr SOUTTAR considered that his amendment was a common sense one and that it met the situation and left it extremely fluid. If it were not passed there would result the ludicrous position that members of the medical profession would be forbidden to make use of the only facilities that were available for them.

The amendment proposed by Mr Souttar was carried by a very large majority.

Dr R A LISTER (Public Health Service representative) hoped that the matter would be referred back. If the resolution as amended was carried it would only hold up to ridicule the decisions of the British Medical Association and the Representative Body. In this matter there were three parties to consider—the pathologists the practitioners and the patients. The pathologists at present were not a well established branch of the profession. He was quite sure that their future lay very largely in the development of pathological facilities by public health authorities. As to the practitioners in his area they were more than glad to have facilities for bacteriological and pathological help provided for them within reasonable reach. With regard to the patients if the resolution was passed and was put into effect a very large number of people all over the country would be deprived of adequate pathological help. The division between the provision for poor patients and that for better-class patients was illogical and administratively unsound. The service must be developed as one service. The matter was a complicated one which could not be disposed of very hastily and he hoped that at the present stage the chairman of the committee would take it back and bring it up for consideration at a future time.

The motion to refer back was seconded from four places in the meeting.

Dr C F DOUGLAS (Fife) supported the proposal to

refer back. Locally they had no experience in Scotland or these conditions. In Edinburgh the public health authorities always dealt with this matter of pathology. The whole of Scotland was covered by the same conditions as held good in Edinburgh. Therefore, the position being so fluid it was very suitable that the motion should be referred back.

Dr S C DYER (Wolverhampton) said there was another element to be considered in the matter—namely the progress of medicine. For any proper advance in pathology there must be the closest possible contact between the patient and the pathologist and that contact could best be brought about by placing the pathological work connected with the individual patient in the laboratories attached to the voluntary hospitals. He hoped the motion even as amended would not be referred back. The future of bacteriologists such as experts in the examination of water or milk possibly did lie with the public health authorities but the future of pathologists as a whole certainly did not lie there but in the laboratories attached to the voluntary hospitals to encourage the establishment of a series of centres attached to voluntary hospitals all over the country offered the most hopeful prospect for the real advancement of medicine.

Dr HAWTHORNE agreed to take the motion back for consideration by the Council. It had been modified by the better judgement no doubt of the Representative Meeting and as the Council had to accept the responsibility he felt in duty bound to ascertain the scope and bearing of the words which had been spatch-headed into his proposal. He would make no allusion to the doctrines which had been preached from that platform in the course of the debate, some of them having their origin in Islington and others in Aberdeen. He would not attempt to controvert or challenge any of those doctrines but as far as his own motion went he accepted the reference back.

It was agreed to refer back the motion.

Dr HAWTHORNE finally moved.

That where a pathologist attached to a hospital or medical school undertaking pathological work as a general service does such work for persons able to pay fees the fees paid for such examination (subject to such charge for the use of the laboratory as may be arranged) should be the property of the pathologist and should be a matter of private arrangement between the pathologist and the person for whom the examinations are made.

He said that this related to the arrangement they thought should obtain between a hospital pathologist and the authorities of the hospital and private patients. Clearly the hospital pathologist had to do the pathological work for inpatients and outpatients of the hospital but he might and often did carry on a private pathological practice the specimens being sent to him at the hospital. Whether that was an ideal course or not did not at this moment arise. In these circumstances it was reasonable that the pathologist should by arrangement pay a reasonable contribution for the use of the laboratory for his own private practice and having done that he should himself fix the fees which he regarded as proper for specimens examined from private patients these specimens being sent from persons who were in a position to pay fees and were under the care of private practitioners outside.

Dr J HUDON (Newcastle) opposed the motion. He said that in Newcastle a pathologist was attached to the College of Medicine and no private practitioner really carried out an examination of a cancerous tumour. He sent it to the college which rendered an account. What happened inside the college was beyond the private practitioner. He suggested that the motion be referred back to the Council. It had been brought up in connexion with London not in connexion with the North Country and he believed the same thing applied to Scotland.

Dr F RADCLIFFE (Oldham) was absolutely convinced that in many parts of the country what was proposed would be unworkable. It would put pathologists as officers of institutions in an extremely awkward position. Engaged as whole time officers of various institutions they were to be asked to pay something out of their salaries back to the hospital for the privilege of using its laboratory. Even if the governing body would agree to such an arrangement which was doubtful would they allow their whole time

paid medical officer to charge whatever fees he liked for work done in their hospital? That would be entirely contrary to the whole procedure of voluntary hospitals. If it worked successfully at first, and a pathologist to a voluntary hospital was giving part of his time to the hospital and part to his paid private work, would there not come a time when some member of the committee of management would say "We are paying our pathologist so much a year, he is giving most of his time to private work, we ought to reduce his salary or get rid of him?"

Dr P. MACDONALD (York) said that his hospital had set up a scheme, his own child, upon the basis that the pathologist worked for the hospital and for private patients, and he did both exceedingly well. What was proposed could be done perfectly well in certain circumstances. Probably in large areas, with large hospitals and ample work for the pathologist's whole time, what was proposed would not work, but in other areas it was being done perfectly well.

Dr R. ST. L. BROCKMAN (Sheffield) said it could be done in large areas also. Sheffield had two general hospitals and a women's hospital, with a pathologist appointed to each, at £500 a year—paid partly by the hospital, partly by the university. The rules agreed to by the staff, the university, and the board of management allowed him to do private work, provided the staff were satisfied he was doing the work of the infirmary. He was allowed to charge for his private work, making his own arrangements with the doctors. With regard to the charge for use of the laboratory no charge was made by any hospital in Sheffield.

Dr H. S. BEADLES (Council) said what was proposed could be done in small areas, and might be done in some large areas, but could not be done in a considerable number of large areas. In the greater number of cases the pathologist was paid a full salary, and could not expect to be allowed to take private work as well. At that moment, on behalf of the Insurance Committee of his area, he was supposed to be negotiating with a hospital as to how it could do pathological work. When he met pathologists was he to make a stipulation on behalf of the British Medical Association is opposed to the Insurance Committee? The plan was not workable.

Dr J. STEVENS seconded the motion to refer the proposal back.

Dr HAWTHORNE said representatives must form their own estimates of the statements of previous speakers. Some misunderstood the general proposition contained in the motion. It related to a hospital pathologist or a pathologist in a medical school undertaking pathological work as a general service, examining specimens and giving reports upon them for the service of the general body of practitioners or any practitioner who came to submit specimens to him. They were not dealing with whole-time servants, but those who had a particular appointment which left them free to cultivate individual activities. Fees for that service should be paid by the individual for whom they were done, and a pathologist doing such work in a public laboratory should pay for the facilities afforded. He urged the Representative Body not to get into the habit of referring matters back because the whole position was thoroughly explored before a definite recommendation was made.

The motion was carried by a two-thirds majority.

#### THE ASSOCIATION'S WORK IN SCIENCE

Dr HAWTHORNE then moved that the remainder of the Annual Report under "Science" be approved. He acknowledged the Association's indebtedness to the experts for their reports on work done by the Association's scholars and grantees. The two reports issued on rheumatic heart diseases in children were generally recognized as substantial contributions to a difficult subject which had close relation to the maintenance of the health of the community (Applause). It was hoped to have a report next year from the Rheumatism Survey Centre at Paddington Green Children's Hospital. As regards the Library, although

the loan period had been extended from fourteen to twenty-eight days, some books were retained beyond that period in spite of repeated applications. Such action was anti-social, and he appealed to members to be loyal to others. His Library was increasingly appreciated. He paid tribute to the winner of the Stewart Prize, Sir Malcolm Watson, and to Dr J. S. Minson, "one of our fellow representatives," on the award to him or the Sir Charles Hastings Clinical Prize, and offered congratulations to Dr James Abston (Edinburgh), to whom the Council had awarded the distinction of honourable mention for a clinical study of great merit. He came next to the Council's general statement and argument on pathology, which was based upon the view that the individual practitioner in pathology was like the individual practitioner in any other department of medicine, that he ought to be governed by the same ethical and general considerations, and occupy the status of an expert in his particular sphere. The general proposition underlying the argument was that, there as elsewhere, personal guarantee and personal responsibility were to be desired. An institution might have an imposing name, but its real value depended upon the competence, the accuracy, and the good faith of the individual doing the work. The whole position in clinical pathology was more or less fluid, and time would determine what particular direction it was in the interests of the pathologist and of the community that it should take. Individual pathologists, as individual practitioners in all spheres, relying upon their own competence, were doing highly scientific and valuable work, and it was in the interests of medicine that the Association should do all that was possible to maintain that position.

Dr L. A. PARRY (Brighton) moved to make it clear that in the general propositions which the Council had adopted with regard to pathological institutes and practitioners (Paragraph 89 of Annual Report), dental practitioners were included throughout. After congratulating Dr Hawthorne on his able and eloquent statement, he said he was sure it was the intention of the Science Committee that dental practitioners should be entitled to report in the same way as medical practitioners.

Dr HAWTHORNE accepted the amendment on the understanding that the Science Committee would put it into suitable words, so as to harmonize with the terms of the resolution.

Dr PARRY also moved to add to the last subparagraph, which read, "That in no circumstances should a pathological report be furnished to any person other than a qualified medical practitioner," the words, "except at the request of the practitioner." He said there were conditions under which it might be advisable that at the request of the doctor it should be sent to the patient. It was a common thing for a visitor who left Brighton before the report was ready to ask for it to be sent on to him, so that he could take it to another medical man.

Mr BISHOP HARRIS said that in such a case there was no reason why the Brighton doctor should not arrange for the report to be sent to him, and he could then pass it on to the patient. That would protect the doctor, but in the interests of the patient it might not be desirable to slow the report to him.

Dr HAWTHORNE could not accept the amendment. A rigid standard ought to be maintained. A professional communication between two medical men should not be left to the risk of inspection by the patient. The doctor could communicate to the patient any information he wished. The amendment was lost.

#### Pathological Institutes

Dr R. FORBES (Gateshead) moved an amendment.

That the Representative Body disapproves of the advertisement in relation to the advertisement of pathological institutes such as is referred to in the foregoing recommendation of Council, and instructs the Council to exclude advertisements of such pathological institutes from the pages of the BRITISH MEDICAL JOURNAL.

He drew attention to the fact that Paragraph 91 of the Annual Report stated, "There is here obvious inequality of opportunity, and though not prepared to

advise the summary exclusion of these advertisements, the Council is of opinion that in some respects they require supervision", yet in the first recommendation of Council members were advised to avoid any association with such enterprises. The two statements were not consistent. There were three different types of institutes and pathological laboratories actually in existence—the hospital type, the limited liability company type, and the type which was run under some trading name for advertising purposes. The British Medical Association had definitely set its face against advertising trading firms. There was a sort of transition type between the trading firm and the hospital, or the private pathologist himself with whom practitioners treated and knew in person. This sort of transition type was somewhat indefinite. Sometimes it was a group of practitioners who ran an institute. Sometimes it was run under the name of a limited liability company. Sometimes it was managed in such a way that one was not quite sure how it was run. The Council evidently thought there was something indefinite and undesirable about that particular type of institute, so much so that they had inserted in Paragraph 91 two particular qualifications which applied to any advertisements appearing in the Journal. What his Division feared and what they believed to be true, was that such institutes and laboratories were cutting fees. It was undesirable that the Association should lend the pages of its Journal for the advertising of such bodies. It was more fitting and consistent that such bodies of a transitional type between the trading firms and the private individual should be summarily and entirely excluded from being advertised in the Journal.

Dr H. D. WOODROFFE (East Norfolk, Norwich) supported the amendment. He said that the policy of the Association was to place the pathologist on the same footing as every other consumer. At the same time, if the Gateshead amendment was not passed the private pathologist was being left to compete with what might aptly be described as mass production. Unless it were possible (and it was obviously impossible) to fix the fees which those aptly termed transitional institutes were going to charge for pathological work, then the private pathologist could not possibly compete with them. If the Association was going to insert these advertisements then in all fairness it would have to allow a private pathologist to advertise, and it allowed a private pathologist to advertise why should it not allow every other consultant to advertise? The Association had a reputation for fairness. If it was going to place any one section of the profession under the disadvantage of unfair competition, it would be laying itself open to the accusation of having lost that reputation.

Dr HAWTHORNE asked the Representative Body to reject the amendment, not that he objected to it as an ideal scheme but they had to deal with a situation which was not rectified by a clean piece of paper. Certain things existed which the representatives might wish did not exist but no pious aspirations would cause them to cease to exist. Certain considerations had to be borne in mind. First of all it had been a custom for some considerable time to allow advertisements of pathological institutes in medical journals. It would be somewhat unjust to exclude summarily a practice which had been countenanced at least by the absence of opposition. While there were some undesirable institutions, there were others which had done good service to the profession, and therefore to the public by providing facilities for pathological examinations when such facilities were not provided in any other direction. Even at the present time there were large areas of the country where no facilities offered by private pathologists actually existed, and it was therefore a convenience for sections of the profession who practised in those particular areas to know of institutions where they could get the work done. It would be an injustice to say that the advertisements of these institutions should be abruptly cut off. If the Association had to start all over again all the members would probably be convinced that advertisement, whether of individuals or of institutions in medical journals was inadvisable. But that was not the position.

The CHAIRMAN of COUNCIL appealed to Gateshead to leave the matter in the hands of the Council without summary

direction. It was not easy to conduct the advertisement pages of a journal without a little care in dealing with individual cases. Summary directions were apt to hit deerving people rather hardly. If it were agreed that the Council's recommendation went very far in the direction that Gateshead wished, and also the other resolutions mentioned by Dr Hawthorne in the way of giving guarantee of reputable work by medical practitioners, and which would be a guiding principle in deciding on advertisements, then he should imagine that enough had been done at present. The amendment would cause such an impression that he was rather afraid to contemplate the trial of the Imperial Secretary and the Medical Secretary in dealing with advertisements.

Dr LOUBES said he did not feel justified in withdrawing the amendment, though he was not altogether averse from so amending it as to bring it into line with some of the suggestions that had been made since he had introduced it.

Dr LOUBES'S amendment was lost and the remainder of the Annual Report or Council under Science was approved.

#### *Scheme for Collective Investigation*

Dr HAWTHORNE next moved approval of the Council's proposals for the carrying out by the Association of the scheme submitted for collective investigation by individual medical practitioners. In doing so he said that everybody would agree that there was valuable clinical information in the hands and heads of medical practitioners. The Council had selected two subjects for investigation—namely, varicose ulceration and the natural history of gastro-jejunal tumours. The whole matter had been discussed by a joint committee formed partly by the Insurance Acts Committee and partly by the Science Committee. That body had done the work under the chairmanship of Dr Douglas.

Dr C. E. DOUGLAS (Council) emphasized the importance of the matter. It was no new thing for the Association to try to bring together the collective experience of its members. In the 'sixties' the Association began collective investigation upon such subjects as the treatment of pneumonia and so forth. The investigation was more or less successful. In the early 'eighties' there was another attempt which was very much more successful. It dealt with subjects like pneumonia, the communicability of phthisis, and other matters information upon which by this time had passed into the general body of knowledge of the profession but which at the time were somewhat moot points. Those investigations were carried out by between six and seven thousand of the members. He wanted the present generation to play up to the work of the past and to remember that the men who went before them were interested not only in £ s d, but in the real work of their profession.

Dr C. E. S. FLEMING (Salisbury) congratulated the Council on its proposal but he wanted to ask the Chairman of the Science Committee what was intended to be done with the returns when they were received. The former inquiries failed because the returns were merely a collection of bald facts and statistics. If the same thing were to happen again the full value of the returns would not be obtained. The suggestion had been made—and he thought it a good one—that when the facts had been collected by the Council they should be discussed at meetings of the Branches and at the next Annual Meeting of the Association in the appropriate Section.

Dr E. V. MACLEAN considered that there was no question at all as to the paramount value of such investigations as those now proposed, but he felt bound to say that the returns received by the Puerperal Morbidity Committee in regard to puerperal infection and the diseases and accidents of childbirth were not satisfactory. They were too few, to begin with, and although some of them were of outstanding value others were not documents from which it was possible to extract any useful information. If in connection with the new undertaking even a few members in each Divisional area could be induced to undertake the work of investigation or to organize it, not only for themselves but for their colleagues, a promising beginning would have been made. The present would not be the first occasion on which such a resolution had been adopted with some degree of enthusiasm. There had been occasions when subsequently the

enthusiasm had faded and nothing very much had resulted. He hoped that the new start would be a real one, and that it would be possible to collect, by appropriate committees at headquarters, information which the general practitioners of the country alone possessed. He strongly supported the motion.

Dr HAWTHORNE, in answer to Dr Flemming, said that steps had already been taken to secure that all the information that was obtained would be collected and presented in a useful form. An assurance had been received from the Ministry of Health that the Association should have the services of one or more experts who were accustomed to deal with statistical returns, experts who would aid in the formulation of proper questions and in the analysis of the answers. In addition to that, Dr A. P. Luff, who had considerable experience as one of the advisors of the Home Office in years gone by, had been approached, and he had kindly consented to act with the joint subcommittee which would deal with the whole of the matter, and to give his time and his experience in helping the Association. As to the suggestion that the results might be discussed in the Divisions and even in one of the Sections of the Annual Meeting, it struck him as being useful and helpful, and note would be taken of it. No doubt Dr Douglas would see that what could be done in that direction was done. If the scheme was to be successful, it must not only be carried enthusiastically in the present meeting, but it must be supported by practical work throughout the length and breadth of the country. The proposals of the Council were approved. This concluded the discussions on the report under "Science," and Dr Wallace Henry left the chair, which was resumed by Dr HAWTHORNE.

### MEDICO-POLITICAL

*Municipal Maternity Hospitals*  
Dr J. W. BONE (Chairman of the Medico-Political Committee), with regard to a resolution passed at the last Representative Meeting, providing that where a general practitioner is called upon to render assistance at a confinement in a municipal maternity hospital, the local authority shall be responsible to him for his fees until the patient is removed from the hospital, now moved.

That inasmuch as the liability of local authorities for the payment of a medical practitioner called in on the advice of a midwife extends over a period of four weeks from the birth of the child, it is not desirable to suggest that the period of responsibility of local authorities should be extended.

This was carried.

Dr R. FORBES (Gateshead) moved to amend the resolution passed last year so that, with the addition of certain words which he proposed, it would read:

That where a general practitioner is called upon to render assistance at a confinement or for any condition arising directly out of parturition in a municipal maternity hospital, the fees payable to such practitioner should not be less than the scale of fees approved by the Ministry of Health for the payment of local supervising authorities to medical practitioners called in on the advice of midwives under Section 14 of the Midwives Act 1918 but that the time limit of twenty-eight days should be removed and the local supervising authority be responsible for the fees of medical practitioners under a similar scale until such time as the patient is removed from hospital. [The added words are in italics.]

Dr Forbes said that under Section 14 of the Midwives Act it was permissible for the local health authority to pay the fees of a doctor for attendance on a patient in a maternity hospital until the twenty-eighth day, but if there was any condition arising out of the confinement which necessitated the patient staying longer than twenty-eight days there was no provision for payment beyond that time. If the patient was in a municipal hospital he considered that she should be looked upon as a charge on the municipal authority, and that until she could be removed to her home and be treated as a private patient the authorities should still be wholly responsible for the fees. If some condition such as phlebitis or pelvic cellulitis, which necessitated a longer stay in hospital, arose it was not reasonable that on the twenty-eighth day the fee to the doctor should cease and that from that day she should be looked upon as a private

patient. Provision for payment should extend over the whole period of stay in hospital.

Dr BONE said that Gateshead had brought forward two motions under one. Each of the two newly inserted clauses should be taken separately.

Dr FORBES agreed to the division of his motion into two parts, and the first part, with the insertion of the words "or for any condition arising directly out of parturition" was accepted by Dr BONE and by the meeting.

With regard to the second insertion, that of the fresh words at the end, Dr BONE submitted that the resolution just carried on his motion rendered this out of order.

The DRUGS CHAIRMAN ruled that the addition of these last words to the resolution of last year was out of order in view of the motion just carried.

Dr R. S. L. BROCKMAN (Sheffield) moved, with reference to the resolution passed last year setting out the kind of cases for whose institutional treatment the local authority should make provision, a further resolution as follows:

That in the case of large towns where there is already in existence a voluntary maternity hospital the municipal maternity home should be primarily for normal cases where the home conditions are unsuitable.

He said that he had been asked to bring this forward on the suggestion of the medical officer of health, who had started his local hospital primarily for patients whose home conditions were unsuitable, and had excluded the other types of cases mentioned in last year's resolution—namely, serious cases of ante-natal complications, cases requiring major operations, and cases where isolation and treatment of septic infection were specially indicated—unless in these also the home conditions were unfortunate.

Dr BONE said that Sheffield suggested a limitation of the resolution passed in 1926. There was no reason why Sheffield or any other place should not limit the use of its hospital if the local conditions appeared to render such a course proper, but if such a limiting motion is Sheffield proposed were passed, other places might be put in a difficulty. He suggested that the amendment be withdrawn, and Dr BROCKMAN, by permission of the meeting, withdrew it.

Dr BONE also moved.

That the principle of remuneration on a salaried basis for consultative services to municipal maternity hospitals is not unreasonable but that the actual salary must be governed by the circumstances of each particular case (that is, the amount of work required and the time occupied) and should bear some relation to the remuneration laid down in the resolution of the Representative Meeting in 1926, which provides that where a consultant is called in by the practitioner in charge of the case the fee should be for the consultation not less than three guineas, and for a major operation not less than ten guineas.

He said that in some districts it had been found desirable to pay the consultant by salary, and the question to be considered was the basis for payment of such salaried consultants.

This was agreed to.

### Administration of Anaesthetics by Dentists

Dr BONE moved the following on behalf of the Council:

That the policy of the Association (as contained in the paragraphs relating to the administration of anaesthetics approved by the Representative Body in 1910 as part of the evidence given on behalf of the Association before the Departmental Committee on Coroners Law, etc.) be amended to read as follows:

- 1 That no person other than a registered medical practitioner should administer any anaesthetic for medical or surgical purposes, except that a registered dentist may administer anaesthetics for dental purposes only.
- 2 That where a general anaesthetic is administered it is undesirable that any person should act both as operator and administrator in the same case where this can be avoided, but it must be recognized that cases occur in practice, especially in sparsely populated districts in which this responsibility must occasionally be undertaken.

He said that the old policy, formulated in 1910, set out that dentists might administer nitrous oxide for dental purposes only, and it had been pointed out by the dentists that such a policy was obsolete, and was not a policy which could properly be advanced to day by the British Medical Association. What was here proposed was an amendment of the old policy.

Dr C T T Scott (Willesden) urged the inadvisability of the Representative Body expressing any additional opinion as to the administration of anaesthetics by dentists. His Division thought the General Medical Council did a wrong thing in allowing registered dentists to receive special instruction and to administer anaesthetics other than nitrous oxide for dental purposes. At the present time dentists were giving anaesthetics very generally. Some dentists were doing nothing else but administering anaesthetics of all kinds for dental purposes only. He had heard that in some country districts dentists administered anaesthetics for general surgical purposes.

Dr BOVE asked whether the meeting would like it to go out after that discussion to-day that they still believed that registered dentists should be permitted to administer nitrous oxide and local dental anaesthetics, but no other anaesthetics. Dentists to-day were trained in the administration of anaesthetics, and many of them were freely administering such for their own dental purposes. This was recognized as a proper practice by the authorities, and surely to-day the British Medical Association could not say to the dental profession that it did not approve. The argument that dentists might become anaesthetists for all purposes was outside the scope of the motion he had proposed.

An amendment by Willesden in the sense of Dr Scott's speech was lost.

Dr W A M SWAN (St Pancras) moved to substitute nitrous oxide for "anaesthetics" in the reference to administration for dental purposes. He considered it undesirable that dentists should themselves administer ether or chloroform.

Dr BOVE said that he could not accept this. It would cut out ethyl chloride, which was a common anaesthetic used by dentists.

The amendment was lost.

Dr H G DALL (Birmingham Central) moved to insert the qualifying words after "dentist," "who has received special instruction in the administration of anaesthetics." His Division thoroughly approved the restatement of policy with regard to anaesthetics, but it felt that the Council had overlooked the fact that since 1920 the *Dentists Register* had been extended to include those persons who were practising dentistry without qualifications, and while it was perfectly true that all newly registered dentists would be instructed in anaesthetics, it was not true that a large number of those at present on the *Dentists Register* had not been so instructed. The position should be made perfectly clear to the public as to the responsibility of any individual who administered anaesthetics.

Dr W A MURRIS (Birmingham Central) also pointed out that dentists themselves had recognized in the regulations for dental benefit under national health insurance the differentiation as between those in their profession who were trained and those who were untrained in anaesthetic administration.

Dr BOVE objected to putting the proposed words into the motion. It was no part of the duty of members of the medical profession to separate the sheep from the goats among their confreres the dentists. That was the dentists' own affair. The resolution should be passed in general terms and applied to dentists as a whole.

Dr DALL urged that the present was an interim period. The *Dentists Register* contained the names of thousands of men who had had no training or experience in anaesthetics.

The amendment by Birmingham was carried by a considerable majority.

#### ELECTIONS

Before the representatives rose for lunch the MEDICAL SECRETARY announced that Dr C O Hawthorne had been elected without a contest Chairman of the Representative Body, and Mr Bishop Harman, also without a contest, Treasurer. (Applause.)

For the office of Deputy Chairman of the Representative Body there were four candidates—namely, Dr. J W Bone, E K Le Fleming, Arnold Lyndon and S Morton Mackenzie—and the result would be announced later.

The election of twelve members of Council by grouped representatives had resulted as follows:

- Dr G B HILLMAN (North of England and Yorkshire)
- Dr I W JOHNSON (Lancashire and Cheshire and North Lancashire and South Westmorland)
- Dr J R PATERSON (Birmingham and North Wales Shropshire and Mid Wales South Wales and Monmouthshire and Staffordshire)
- Mr E B TURNER (Metropolitan Counties—Inner Group)
- Dr W PATERSON (Metropolitan Counties—Outer Group)
- Dr H C BRISTOWE (Bath and Bristol Dorset and West Hants Gloucestershire South Western West Somerset Wiltshire and Worestershire and Herefordshire)
- Dr A LYNDON (Kent Oxford and Reading Southern Surrey and Sussex)
- Dr G W MILLER (Aberdeen Dundee Edinburgh Fife Northern Counties and Perth)
- Dr J PATRICK (Border Counties Glasgow and West of Scotland and Stirling)
- Dr R C LEACOCKE (Connaught Leinster Munster and South Eastern of Ireland)
- Dr J ARMSTRONG (Ulster)

In the East York and North Lincoln Cambridge and Huntingdon Essex Midland Norfolk South Midland and Suffolk Group there had been a contest which had resulted in a tie. In accordance with standing orders it was necessary to count the number of constituents in the electing group and on that basis Mr A M WEBER was elected with 949 constituents as against 899 for Dr D G Greenfield.

Dr HAWTHORNE returned thanks for his election, but said that anyone with the history of that chair in his mind must approach its responsibilities with some degree of trepidation.

#### Election of Deputy Chairman

On the resumption of the meeting after lunch, the MEDICAL SECRETARY announced that Dr Arnold Lyndon had been elected Deputy Chairman of the Representative Body.

#### MEDICO-POLITICAL (continued)

##### The Administration of Anaesthetics

The discussion on the motion of the Chairman of the Medico-Political Committee proposing to amend the policy of the Association with regard to the administration of anaesthetics was continued.

Dr H G DALL (Birmingham) moved a further amendment to the last line of the motion, so that instead of reading "this responsibility must occasionally be undertaken" it read, "this responsibility may justifiably be undertaken." The phrase as it stood did not meet the position of the practitioner who gave an anaesthetic in the later stages of a confinement or of a forceps operation. Cases occurred, especially in sparsely populated districts, in which the responsibility might justifiably be undertaken.

Dr BOVE accepted the amendment which was agreed to.

Dr J T D EWART moved to omit the words "especially in sparsely populated districts" and Dr PETER MACDONALD seconded. Dr BOVE said the question of single-handed anaesthetic administration arose more frequently in sparsely populated districts than in those densely populated but as leaving out the words would not affect the proposition he had no objection to their omission.

The amendment was carried.

Dr TEMPLE GREY (Marylebone) proposed that the amended recommendation be referred back to Council. It did not suffice to be specially trained in the administration of anaesthetics. It was necessary to know how to treat a case when something went wrong. In the case of a fatality under an anaesthetic the only person who would be in a reasonable position before a coroner was a duly qualified medical man. Referring to the first part of the resolution, he said the Association had no concern with deciding what dentists had to do.

Dr E A STANLEY (Lunbridge Wells) seconded the reference back, which was not carried.

The CHAIRMAN then put the motion as revised—namely

1 That no person other than a registered medical practitioner should administer any anaesthetic for medical or surgical purpose except that a registered dentist who has received special instruction in the administration of anaesthetics may administer anaesthetics for dental purposes only.

2 That where a general anaesthetic is administered it is undesirable that any person should act both as operator and

administrator in the same case where this can be avoided, but it must be recognized that cases occur in practice in which this responsibility may justifiably be undertaken.

The motion was carried by the necessary two-thirds majority to make it the policy of the Association.

#### *Anaesthetics in Connection with Dental Benefit*

Dr BONE moved as a recommendation of Council

That the fees for medical practitioners administering anaesthetics for dental operations (as an additional benefit under the National Health Insurance Acts) be as follows: (a) For the simple administration of nitrous oxide or a similar anaesthetic, 10s 6d if only one patient is dealt with, but if more than one patient is dealt with at the same time and place the fee should be 7s 6d per patient, and (b) that for other administrations, whatever the anaesthetic, the fee should be one guinea.

Mr McADAM ECCLES asked for an explanation of the words "simple administration." Dr BONE said they were used in comparison with a prolonged nitrous oxide anaesthesia.

Dr J B WILLIAMSON (South Shields and Tyneside) moved to amend the recommendation by the insertion of the word "minimum" ["minimum fees"]. He said Dr BONE assured him this could not be done, but his Division instructed him to move the amendment, and as it was "a very little one" he moved it. (Laughter.) Dr BONE said they were hoping to get the Ministry of Health to adopt this scale, and there must be definite fees for certain services. The amendment was lost.

Dr NRYLL CROWE (Worcester) moved to amend the recommendation by making the fee for administration of an anaesthetic in all cases one guinea. Personally he did not agree that a guinea should be given in every case, but that was the amendment he was instructed to move.

Dr BONE did not think there were many optimists who thought there was a chance of getting more than half a guinea from the Ministry of Health for a simple gas administration.

The amendment was lost.

Dr J MACKINNON (Sheffield) also moved to amend the recommendation by making the fee for the administration of nitrous oxide or similar anaesthetic half a guinea in all cases. He said there was some feeling in his Division that a fee of 10s 6d was too low, and they certainly thought it should not be reduced to 7s 6d, chiefly because fees for the administration of anaesthetics were not fixed on a time basis but on a basis of responsibility. The responsibility did not get less according to the number of cases in which an anaesthetic was given.

Dr BONE said Sheffield had raised a practical point, but it was a point to which great attention had been given in committee, and eventually it had been decided that it would be better to make a reduction to a person "taking a quantity." It was a principle which had been adopted on many occasions. Evidence had been received from men who were in the habit of giving anaesthetics for dental purposes to the effect that they were quite satisfied to accept a fee of 7s 6d. They had stated that perhaps the whole morning was occupied in giving anaesthetics or dental purposes, and that their remuneration for all the morning's work was satisfactory to them at the 7s 6d rate. When men of certain standing who were doing that sort of work were satisfied with the rate of pay, the committee naturally hesitated to suggest anything higher.

The amendment was lost by 52 votes against 47.

Mr McADAM ECCLES (Council) moved the deletion of the word "simple" from the motion ["the simple administration of nitrous oxide"]. All who had given nitrous oxide were aware that it might be simple administration or it might not be.

Dr BUILDON seconded the amendment.

Dr J LIVINGSTON (Furness) said that the amendment would completely alter the intention of the motion. For a simple administration of nitrous oxide a fee of 10s 6d was suggested, but where other administrations, whatever the anaesthetic, including nitrous oxide, were given, the fee was going to be a guinea. Now the position arose that for an administration of nitrous oxide, whether it was

short or long, simple or complicated, a practitioner was only going to get 10s 6d for one case, and if more than one, 7s 6d. If he might suggest it to Mr ECCLES, the addition of the word "short" would have put the matter right, but by leaving out the word "simple" the whole intention of the motion was altered.

Dr BONE agreed with Dr LIVINGSTON. The omission of the word "simple" would alter the whole meaning of the motion, and would reduce the fees payable to practitioners for all long administrations of nitrous oxide, and, more important still, he would direct attention to the other words "or a similar anaesthetic." "Similar anaesthetic" particularly applied to ethyl chloride, which was an anaesthetic commonly used by dentists. The simple administration of ethyl chloride was a matter of seconds, but ethyl chloride might be given continuously by the open method of administration, and the administration might be prolonged almost indefinitely. That second kind of administration of ethyl chloride they would consider to be not a simple administration, and they would expect to get the fee of a guinea for it. The effect of the amendment, however, would be that such administration would come under the 10s 6d or the 7s 6d fee, which would not be at all a satisfactory fee for such administration.

The amendment was lost.

The recommendation of Council was then put and carried by a substantial majority.

#### *Payment for Ante-natal Work*

Dr BONE next moved, as a recommendation of Council, relating to a resolution passed last year.

That it is inadvisable to press for the amendment of the Midwives Act 1918, in order to secure that local authorities be made responsible for ante-natal work to any greater extent than is at present the case.

He said that last year the Representative Meeting instructed the Council to consider the advisability of pressing for the amendment of the Act in order to secure that local authorities should be responsible for payment for ante-natal work. The recommendation of the Council needed a little explanation. At present every insured practitioner was responsible, as part of his contract, for ante-natal work for such of his patients, being women, as were insured persons. Therefore that group was already adequately dealt with. Another group of women was dealt with by way of ante-natal clinics, and the remaining women who needed ante-natal treatment were dealt with under the ordinary conditions of private practice, or under the Poor Law. The Council did not think it would be wise to attempt to get any modification of the Midwives Act that would secure a fresh form of treatment paid for by the local authorities for doing ante-natal work. He would wait for further discussion before developing any arguments in favour of the recommendation.

Dr M W RILSON (Dutford) said he had been instructed by his Division to put it to the Representative Body that the motion be referred to the Council with an instruction to consider the Midwives Act of 1918 in the interests of all concerned in ante-natal work, especially in relation to the responsibilities of the general practitioner. His Division was disappointed that the Council did not take the opportunity of the instruction of the Representative Body last year to go fully into the trouble of the general practitioner in relation to ante-natal work, and was rather concerned at the present somewhat negative motion regarding the Midwives Act. Those he represented were not specially interested in the second part of the motion, because they felt in their part of the world, that local authorities should not be given any greater responsibilities than they had at present; they were taking far too much responsibility upon themselves. His Division was now fighting it very hard though not contentedly, and was making preparations to enable the general practitioner to take up the work. It had had clinics, papers read by gynaecologists, and conferences with the county authorities. The county medical officer of health was in sympathy with their requirements and demands, but suggested that he could not do anything until the Midwives Act, 1918, was amended in some way. What was happening was that the ante-natal work at present

being done by a whole-time outside practitioner, in addition to which the county authorities were educating midwives to do practically the whole of the work which ought to be done by the general practitioner. His Division claimed that it was most difficult for the general practitioner to carry out his duties in emergency midwifery work if he was not given an opportunity of coming in very early in the preventive work which he could do in ante-natal matters. They felt therefore that it was unfortunate that the Council should put the motion forward as if the Midwives Act did not require amending. And his source of legitimate work was being cut away from the general practitioner. The Council would do well to investigate the whole of ante-natal work in relation to the general practitioner. It would be a pity for the recommendation to go forward as then it would look as though the British Medical Association were contented with the Midwives Act or that it was powerless. He hoped it would be referred back to the Council so that they might get into the whole of the difficulties of the general practitioner in regard to the matter.

Dr C F S FLEMING (Salisbury) supported the amendment. He considered that if there was one point in which the general practitioner required protection it was in regard to the question of ante-natal examination and the necessary treatment. He hoped the Council would consider this very carefully. The amount of work proposed to be done by local authorities through their health visitors was he thought more than was generally recognized. The form of report by the health visitor was really ridiculous. The gynaecous health visitor was expected to answer included to example question about pelvic measurement. The only remedy he could see at present was for the general practitioner himself to do the work whether he was asked to do it or not. Medical men ought to do everything they could to keep the matter in their own hands.

Dr H M RAYN (Ipswich) also supported the amendment. In Kent, he said, all the midwives were sent for to the central town or the district where they were to be trained in ante-natal work on a three day course.

Mr H M STURTEON (Kennington) thought that the case was now an opportunity for general practitioners to keep a very important part of medical practice in their own hands. If it was allowed to slip into the hands of whole-time officials and nurses, gradually the whole midwifery practice would be done by the latter people.

Dr J MIDDLETON MARTIN (Gloucester) said that ante-natal work would be one of the most important branches of medical work in the future, and doctors ought to do everything they possibly could to develop it. The persons in whose hands it lay most effectively were the general medical practitioners. He would not for a moment oppose the reference back or the motion to the Council although he did not know that there was much to be gained by that course, but he thought it most important that the Council should have the matter constantly in mind.

Dr BOVE said that he should be quite content to support a reference back to the Council of the whole question of ante-natal treatment and the method of carrying out ante-natal treatment *qua* the private practitioner. What was wanted was a thorough inquiry into the methods by which women might get the proper ante-natal treatment which they ought to have and which it was the duty of the medical profession to give them. It was necessary to find out how the private practitioner might be best used to secure such treatment. He suggested to Dr RENTON that his amendment should ask the Council to consider the whole question of ante-natal treatment and the best way in which it might be carried out by the private practitioner.

Dr RENTON and he was willing to accept this suggestion. Sir EWEN MACLEAN thought that the word "financially" should be inserted in the resolution before the word "responsible."

Dr RENTON asked whether his amendment could be put as a separate motion. The CHAIRMAN ruled that it could be moved as an amendment to the motion that the remainder of the Report or the Medico-Political Committee be approved, but that it could not now be moved as a separate motion.

With the leave of the meeting, Dr RENTON withdrew his amendment on the understanding that he would be able to propose it at the stage indicated by the Chairman.

The motion as moved by Dr BOVE was then agreed to.

### Orthopaedic Treatment

Dr BOVE moved on behalf of the Council

That the specialist work of orthopaedic treatment whether at hospitals or clinics should not be done by whole-time officers but on a part-time basis by surgeons who need not necessarily be devoting all their attention to orthopaedic work.

He pointed out that the orthopaedic clinics were springing up in the country and in many instances the general practitioner was being completely shut out from taking any share whatever in orthopaedic work. The Council had produced a very elaborate report on the subject, which appeared as an appendix to the Annual Report of Council, and he commended it strongly to the notice of the representatives. It was on the basis of that memorandum that certain motions which the Council was bringing before the Representative Body that day had been framed. The basic principle of these motions was that the general practitioner should be allowed to take an important part in orthopaedic treatment in the hospitals and clinics. This first recommendation brought orthopaedic work into line with the Association's policy in other directions.

Dr F J HARTLEY (Windsor) moved to amend the recommendation so that it would read

That orthopaedic treatment whether at hospitals or clinics should be undertaken by those who have special knowledge of the subject and as the needs of the patient to receive the most experienced handling are paramount no restrictions should be placed on the appointment of full-time officers.

His Division considered that orthopaedic treatment should be undertaken by those who had special knowledge, and that no restriction should be placed on the appointment of full-time officers. Orthopaedics was highly skilled work and not a work of emergency. Tendon transplantation in infantile paralysis for example could be carried out by an orthopaedic surgeon. Mr Girdlestone of Oxford was attached to their hospital at Windsor and came once a month to see each orthopaedic case—it was not necessary for him to come oftener—and every week he had a clinic to which he sent his assistant and his head nurse. Why should hospitals not be allowed to have the best advice they could get?

Dr HENRIETTA JEFFES (Lambeth and Southwark) supported the amendment. Her Division was unanimously of opinion that orthopaedic work was specialist work, and could not be adequately performed except by those who were doing orthopaedics and nothing but orthopaedics.

Dr C F OLDENBROW (Liverpool) also spoke in favour of the Windsor amendment. He would be sorry to see the official policy of the Association take the direction indicated in the Council's recommendation.

Dr E R POTTEINGILL (Brighton) said that there were one or two fallacies in the Windsor amendment. Nobody denied that the interests of the patient were paramount, but when policies had to be settled two points had to be considered—the interest of the patient and the interest of the doctor. It might be in the interest of the patient that the specialist alone should see him—though he questioned it—but it was certainly not in the interest of the general practitioner. The medical student of to-day who was joining the ranks of general practice was more competent to do this class of work than the general practitioner of an older generation and if all this work was going to be relegated to a whole-time service where was the coming practitioner to get his experience. The dangers of these schemes for orthopaedic treatment as was pointed out in the appendix were (1) the establishment or yet another segregated public health service (2) the withdrawal of a large number of cases or a special type from hospitals in which medical education was carried on, and (3) the ignoring of the general practitioner altogether, or his perfunctory use in connexion with the work. Was it to the interest of the patient that these three conditions should exist? They would come about in specialist intrusion on private medical practice were unchecked and it watertight compartments in medicine continued to be made. The general practitioner would cease to exist. On the other

hand, a specialist who dealt with nothing but his own specialism was of no use in comparison with the general practitioner.

Dr R G GORDON (Bath) also spoke in favour of the motion and against the Windsor amendment. They had to distinguish, he said, between theory and practice. What actually happened in practice was that if whole-time officials were appointed, especially to clinics, the general practitioner in the district was very apt to lose his interest in simple cases, and anyone who was crippled or who seemed to be suffering from anything like an orthopaedic condition was sent to the clinic. The whole-time specialist looked upon these cases with a "single eye," and one constantly found that these children were brought up and treated as orthopaedic cases only, with no consideration for other conditions. Therefore it was essential that the general practitioner should be brought into the scheme as much as possible, so that he could check the work of the whole-time specialist, if it was absolutely necessary that such a person should be appointed.

Mr McADAM ECCLES (Council) described himself as a general surgeon who had perforce to take orthopaedic cases. Orthopaedic surgery seemed to have got into a very anomalous position, because there was a considerable difference of opinion as to what particular class of cases did not fall within its limits. A great deal of glamour had been thrown over the question of orthopaedic surgery. It was not such a wide specialism as it was now made out to be, but he was quite convinced that in the proper treatment of early orthopaedic cases it was essential that there should be co-ordinated work. The people who should be co-ordinated were (1) the general practitioner first and foremost, (2) the specialist, who understood a good deal about anatomy as well as about operative treatment, (3) the mother or nurse of the child, and (4), by no means least important, the child himself. In these orthopaedic centres or clinics all this could be done. Therefore he felt that a whole-time orthopaedic surgeon was wanted—whole-time in the sense that he was doing orthopaedic surgery as a specialty, but there must also be the general practitioner, and there must be co-ordinated work with those in domestic charge of the child. He was in favour of the motion, with the proviso that there should be specialist orthopaedic surgery.

Dr S C DYKE (South Staffordshire) supported the Windsor amendment. Orthopaedic surgery demanded such a specialized technique as hardly to fall within the province of the general surgeon at the present time, but it was to be hoped there would be the closest co-operation between the orthopaedic surgeon and the patient's own doctor.

Dr BONE said the point of the motion was that they should turn up men in each locality who were capable of doing the work on a part-time basis, and that it should not be put in the hands of whole-time specialists who were flying about the country in motor cars and lived miles away from the area in which the work was done.

Dr HIRSHWY, replying, said that sentiment did not enter into the question, which was, "What is the right thing to do, not only for the patient, but for the profession?" The general practitioner could always see his cases at the clinic and, if he wished, attend to them. Mr McAdam Eccles struck the nail on the head when he spoke of co-ordinating the work. It should be the aim of the British Medical Association to co-ordinate every branch, from the general practitioner to the specialist. No general practitioner could keep up to date in every branch; they must have specialists. It was best, not only for the profession, but for the general public.

The Windsor amendment was lost by a large majority.

Sir RICHARD LUCE said that to pass a recommendation so general and sweeping as that proposed by Dr Bone seemed to him to be dangerous. Admiration in surgery was might not be specialization, though it was.

Dr BUILDON seconded the motion along any particular line.

Dr J LIVINGSTON (Furness) said that whole-time officers would completely alter the intention of using their skill in a simple administration of nitrous oxide, an advantage of which was suggested, but where other administration of the anesthetic, including nitrous oxide, question whether fee was going to be a guinea. Now the patient "operating for an administration of nitrous oxide,"

surgeons," declined to be an interpreter of terms, but said that if as a private individual he were asked what he meant by "surgeon" he would say "a qualified medical practitioner who practised surgery."

Mr E W G MASTERMAN (Camberwell) thought there was a general feeling that the motion went a little too far, and he proposed an amendment (which was seconded from more than one place in the meeting) whereby it would read:

That the specialist work of orthopaedic treatment, whether at hospitals or clinics should not usually be done by whole-time officers, but may be undertaken, on a part-time basis, by surgeons who need not necessarily be devoting all their attention to orthopaedic work.

Mr H S SOUTER (Council) hoped the motion would not be watered down by the passing of the amendment. The meeting should understand clearly that they were gradually coming to a definite pass in practice. Was practice going to be carried out in general by whole-time men or by men who were in general work? There was a strong tendency at present—partly with a view to economy and partly because they hoped to obtain greater efficiency (as he thought wrongly)—towards the employment of whole-time men in the strict sense of the word. Personally he thought it was a mistake. The man who was engaged in a general practice, whether he were a surgical specialist, a physician, or what was commonly known as a general practitioner, could deal with any specialty which he chose to take up in a far better way than could the man who was simply employed as a whole-time man on one job. He could take a much broader view of the whole subject, he came into more intimate contact with a larger body of people, he was not simply confined within the four walls of one small subject, and he did better work. Therefore, Mr Souter objected very strongly to the Windsor amendment, which suggested that it was against the interests of the patient that the general practitioner should be employed. One or two of those who had been mentioned as excellent orthopaedic surgeons, personal friends of his own, were by no means whole-time men. They were engaged in orthopaedics as a specialty, but they were not, within the meaning of the phrase used, whole-time officers. They were engaged in orthopaedics as their whole specialty perhaps, but that was a very different matter from being a whole-time paid officer of some concern. He hoped the representatives would take a strong line against limiting work to the whole-time men, whether it was in orthopaedics or in pathology, or in any other subject. The matter should be left open to the widest possible field. Though there was a group of very eminent men who were devoting the whole of their time to orthopaedic surgery, the vast mass of orthopaedic surgery in this country was being done, and being done very well, by general surgeons. He hoped the motion would be passed in its original form.

The amendment by Mr Masterman was then put and lost. A REPRESENTATIVE asked if the motion as it now stood prohibited Mr Masterman, who was a whole-time officer, from ever touching an orthopaedic case. The Drury CHAIRMAN replied that that was a question for Mr Masterman; it certainly did not concern him as chairman.

Dr HENRIETTA JENES moved the omission of the words after the word "basis." Her Division felt that in orthopaedic clinics run by a man who possibly was doing general work all the week and spent half a day or some such time doing orthopaedic work was "not good enough." The orthopaedic work should be really first rate, and the results could without doubt be immeasurably improved if the work was done by people engaged in the particular branch of surgery concerned.

This amendment was not seconded, and therefore fell to the ground.

The motion proposed by Dr Bone as it originally stood was carried.

Dr BONE next moved "That existing local institutions should be utilized to their fullest extent," and this motion was adopted.

Dr BONE further moved

That the private practitioner should have free access to work at hospitals and clinics for the purpose of education and training, and that his services should be fully utilized, giving him a definite position in the scheme both at the clinic and in the domiciliary care of cases.

In answer to a question with reference to the meaning of the words "free access," Dr Bono said that it was the Chairman who had already remarked, the words must have a little common sense read into them. They meant that every practitioner should have reasonably free access to every clinic and every patient. They meant something more than that practitioners should have access to see, and consult about, their own patients.

Dr H M RIVEN (Thurton) said that in Kent there was not free access. The county council had a scheme run by a specialist, who consulted at the hospitals and managed the clinics, but would very soon be overpressed with the work at the clinics, and as it was he left a good deal of the work to nurses, massagers, and such people. The medical men in Kent were tied up and they did not quite know how they were going to fight the matter, but his Division had suggested to its members that any of those practitioners who felt keen on orthopaedics should send in their names and that they should be offered to the county council as clinical assistants. They realized that not all general practitioners were capable of taking on or willing to take on all the orthopaedic work of the county council but at the same time there were people who were quite capable and who should take part in that work. Division might very well get together those people who were keen and offer them as clinical assistants in connexion with those county schemes which were at present run on a whole-time basis.

Dr LEWIS LLOYD (Council) dissented from the definition of "free access" given by the Chairman of the Medico-Political Committee. The difficulty involved was not a hypothetical one. Surgeons were very chary of discussing a case with another practitioner when they knew that the practitioner in charge of the case was in the room. There ought to be a very authoritative definition of "free access" given so that representatives would be able to advise the members of their Divisions when they returned to their constituencies.

The motion was carried.

The final recommendation of Council moved by Dr BOVE, was as follows:

That the arrangements laid down in the British Medical Association's scheme for school children and maternity and child welfare clinics should apply equally in regard to orthopaedic clinics (vide *Handbook* p 192).

He said this meant so far as the arrangements were applicable.

Dr H D WOODROFFE (East Norfolk) moved to add the following words to the recommendation:

but that efforts should be made to secure that a more stringent scrutiny be exercised in deciding which cases are or are not necessary than has been done under comparable schemes for medical examination and treatment by education authorities.

He said his Division felt that the conduct of the various clinics run by local education authorities should be tightened up. There was a tendency for school medical officers to send cases direct to the general hospitals without consulting or notifying the patient's family doctor. Also in rural districts parents sent their children to elementary schools only because there were no others. Many of them could afford and would be willing to pay for private treatment but all cases were lumped together by the education medical authorities as people who could not afford to pay for treatment and were told to go to the hospital. This was victimization of the general practitioner and possibly even more so of the honorary staff of hospitals.

Dr E R FOTHERGILL submitted that the words proposed to be added were really in order to the motion.

The DEPUTY CHAIRMAN ruled that they were an amendment and were in order.

Dr BOVE said he had no special objection to steps being taken to do what was suggested in the additional words, though they were hardly the sort of words to add to a formal motion.

No amendment was carried, and also the motion as amended.

#### MEDICAL OFFICERS OF PUBLIC SCHOOLS.

A series of recommendations were next moved by Dr BOVE relating to the conditions of remuneration and employment of medical officers of public schools. The memorandum and consequent recommendations relating both to whole-time and part-time officers appeared in the Annual Report of Council (SUPPLEMENT, April 23rd, p 149).

By such recommendations, he said, the Association was leaving its ordinary routine detailed work and opening up a wholly new class of work. The Association had been asked by some of the representatives of the whole-time medical officers of public schools to consider the question of establishing such a policy, and that request had been met by the formation of a subcommittee of the Medico-Political Committee, called the Medical Officers of Public Schools' Subcommittee, which had elaborated a policy and had submitted it to the Council. After emendation by the Council the policy was now submitted to the Representative Body. The first motion to the effect that the whole-time medical officer of a public school should be appointed by be directly responsible to and have direct access to the governing body of the school was perhaps the most important of the whole number at any rate it was the motion to which he believed the greatest importance was attached by the group of medical officers concerned.

Dr PETER MACDONALD moved the reference back of all the recommendations on the ground that he desired the conditions which were implied in the series of motions to have a chance of being workable. There had been no preliminary discussion with the headmasters of public schools or with the governing bodies. What would happen if the meeting passed the motions and held them up as a sort of pistol to the school authorities and to the headmasters? He felt certain that the headmasters and governing bodies would have nothing to do with the matter and that both the medical officers of public schools and the British Medical Association would run the risk, to use an Old Testament term of being told to "go to." He thought a proper preliminary would be to get into touch with the headmasters by means of the headmasters' conferences, learn what they had to say about the policy, and get into liaison in that way. There could not be any urgency about the matter.

Mr E W G MASTERMAN seconded the amendment.

Dr BOVE said he quite agreed that sooner or later consultations must take place with other bodies, but surely there was time enough for consultation when the representatives had decided among themselves what they wanted. He suggested that Dr Macdonald's motion should properly come after the meeting had learned something about the proposals—namely, at the end of the series of motions referring to public schools. It would not be wise to confer with the headmasters until the meeting had agreed to a policy.

Mr E B TURNER (Kensington) hoped the meeting would not carry the amendment to refer back. The matter was one which had been brought before the Association as a very urgent demand. It had been remitted to a committee consisting of picked men together with men who knew a great deal about and had a good deal to do with, the management and the amenities of public schools. The matter had been thoroughly thrashed out by that committee, and had been submitted again to the Medico-Political Committee which had sifted it thoroughly. It had then gone before the Council, which again had thoroughly resited and reconsidered it, and had finally passed it for consideration by the Representative Body. He associated himself with every word Dr Bove had said about the inadvisability of referring the matter back before the meeting had considered it—before, even, it was known whether the meeting had any policy in the matter, whether it wished to lay down a policy, or whether it desired to interfere at all in the matter.

Mr JENNER VERRILL who was received with cheers, entirely supported the view that the representatives should proceed to discuss the matter and not refer it back. If a conference at the present stage was sought with the head-

mastics, they would say, "What is this matter which you are bringing before us?" and they would have to be told that when the question, in a consecutive series of well discussed and considered motions, had been brought before the Representative Meeting, that meeting had been afraid to crystallize its views until the views of the headmasters had been heard. In his opinion it was necessary to go to the headmasters and the governing bodies and to say to them, "These are the distinct views of the Representative Meeting."

Dr F RADCLIFFE (Oldham) asked the meeting to consider one point. If it discussed the matter at once and decided upon it, it would probably decide by a bare majority. If, after that, the Association went to the headmasters and to the governing bodies, it would require a two-thirds majority before it could change its views. The representatives were handicapping themselves considerably by deciding upon anything at the moment before they knew what the other side would want, because they would be putting themselves in the awkward position that they could not reverse their policy, even if they thought it necessary, without a very much bigger majority than they could get now.

Dr FOTHERGILL (Brighton) asked if it was a fact that if now the meeting adopted the motion it necessarily involved a policy?

The DEPUTY CHAIRMAN replied that unless the motion was carried by a two-thirds majority it would not have the status of a declared policy of the Association. It might be expressed as the opinion of the meeting, but not as a declared policy of the Association.

Dr F W GOODBODY (Marylebone) desired to ask Dr Radcliffe one question. If the representatives followed Dr Peter Macdonald's proposal, on what were they going to the headmasters? They could only go to them on a decision of the Council, and they could not give them the slightest authorization to think that the Representative Body would not turn down the results of the conferences. It would be wise for the meeting to formulate some kind of policy which could be discussed with the headmasters and governing bodies.

Dr H M RIVER (Thurton) said he had not heard mentioned the Medical Officers of Schools' Association, which had sent up the matter for the consideration of the meeting. Could not the meeting give the proposals general approval? No doubt the medical officers had already discussed the matter with their headmasters to a certain extent.

The CHAIRMAN OF COUNCIL said that there was here a new deprivation—and he believed a useful deprivation—in regard to health policy, and it was essential that it should be launched under the best possible auspices. In his short experience of the Association he had seen two or three admirable decisions in regard to policy seriously prejudiced by the fact that the meeting had passed resolutions (they had been decisions of the Representative Body), and the first knowledge received by the people who had had to pay the bill and suffer such consequences as might accrue, was through the launching of the information in the public press. That had produced a feeling of resentment on more than one occasion, and had created an unfavourable atmosphere, and sometimes a passive or even a very active resistance which had postponed for a long period what might have come into operation in a very short time if the matter had been dealt with in a different way. He wanted members to discover a method by which they could discuss the propositions and alter them if necessary, and not tie their hands by making the decisions operative decisions until they had had the opportunity at the end of the discussion, of deciding whether they would remit to the Council the task of obtaining the opinions of headmasters, and, it might be, of parents and of governing bodies, before the proposals were put into their ultimate form. He was sure that along those lines lay the true path of statesmanship in regard to a project which they all had at heart.

After some private conference,

The DEPUTY CHAIRMAN said that the position had been considered at the table, and the simplest way out of the difficulty would seem to be to ask the press not to report

the discussion. The matter was in a tentative state and was not yet in a very definitely formal position. What was wanted was to get the opinion of the representatives broadly upon the different propositions. After that opinion had once been declared, the whole matter might, if the representatives so decided, go back to the Council, and the Council would conduct any negotiations with the advantage of having had an expression of the opinion of the Representative Body, such opinion not being declared as the formal policy of the Association. In conclusion, he asked whether the meeting would authorize him to invite the press to recognize the position which he had just stated and to abstain from making public the discussion upon the matter.

It was decided that the general press should be requested not to report the discussion.

Dr RADCLIFFE asked how the Representative Meeting could pass a resolution upon a matter, in regard to which two months' notice had been given in the JOURNAL without its becoming the policy of the Association.

The DEPUTY CHAIRMAN replied that it could do so by abstaining from carrying it by a two-thirds majority. The meeting, he was sure, would be able to devise some means of protecting itself from restricting its liberty in future. He would take the responsibility of seeing that that was done.

Dr FOTHERGILL drew attention to Article 33, and said that under it, if the Representative Meeting did not go into committee, if it adopted a resolution that resolution would *ipso facto* become the decision of the Association. He therefore urged that the meeting should go into committee.

Dr MORISON MACKENZIE then proposed, and Dr WALLACE HENRY seconded, that the meeting should go into committee.

The CHAIRMAN OF COUNCIL thought that the proposition was a very excellent way of dealing with the situation, but he considered that one safeguard should be set up—namely, that the rules of debate and procedure should be those of the standing orders and not those of an ordinary committee.

Dr PETER MACDONALD said that he had not wished in any way to brake discussion upon the proposals, which he considered to be very excellent, but he wished them to be considered in the best atmosphere. He was quite willing to withdraw his resolution, on the understanding that at the end of the discussion it would be competent for himself or someone else to move that the matter be referred to the Council.

#### Proceedings in Committee

The Representative Meeting then agreed to go into committee, and the representatives of the lay press withdrew.

Dr BONE moved afresh the motion that the whole time medical officer of a public school should be appointed by the governing body of the school. He said that, in drawing up this and subsequent recommendations the Medical Officers of Schools' Association had been consulted, and representatives of school medical officers were on the committee which originally formulated the proposals. The first recommendation, which was very important, challenged at once the methods of election and of responsibility which were at present in vogue, at all events in some of the public schools.

The recommendation was supported by Dr E H LE FLEMING, who spoke from his own experience as a part-time officer.

The recommendation was carried unanimously and without further discussion, as were other recommendations—namely that the medical officer should be a medical practitioner who had had experience in practice, including experience in special branches of medical work, that the possession of a qualification in public health work should be an additional advantage, that the minimum commencing salary for a maximum of 500 resident pupils should be £600 a year, plus £1 per head per annum for

each resident pupil in excess of 500, and that, in addition, the medical officer should be provided by the school authorities with a suitable house or an adequate allowance in lieu thereof that the initial salary should be subject to periodical increments, to be determined between the officer and the governing body at the time of appointment, and that the medical officer should not be responsible during the intervals between school terms, for any medical attendance given to pupils other than those remaining at the school owing to illness. Dr BONE remarked, in moving this list that present practice and custom had to be considered.

The next recommendation set out the list of duties of a whole-time medical officer of a public school. The list appeared in Paragraph 131 of the Annual Report of Council (SUPPLEMENT April 23rd). Dr BONE said that the list had been arranged with great deliberation and had been subjected to much criticism before appearing in its final form.

Dr MIDDLETON MARTIN asked whether there was a distinction between new pupils and resident pupils for he noted that the first duties were "examination of all new pupils on admission to the school," and "periodical examination of resident pupils."

Dr I. W. COODBOO, a member of the committee which had formulated the proposals said that the committee considered that all boys entering the school should be examined for grubs, but that periodical examination should be limited to resident pupils. If periodical examination of day boys were done the result would be to take them out of the care of their ordinary family doctor.

Dr MIDDLETON MARTIN moved that periodical examination should apply to all pupils day or resident.

The time of adjournment (6.30 p.m.) having arrived the discussion was left at this point, it being understood that the matter would be resumed as first business still in session on Monday morning.

#### Monday July 18th

The chair was taken at 10.15 a.m. by Dr BRACKENBURY, who was welcomed back after his brief illness with long continued applause. In reply to the greeting he said how sorry he had been to cause any interruption of the ordinary course of business of the Representative Body and how much he appreciated all the kind inquiries and expressions of sympathy he had received.

#### WHOLE-TIME MEDICAL OFFICERS OF PUBLIC SCHOOLS

The Representative Meeting immediately went into committee to consider the remainder of the report on medical officers of public schools and the representatives of the lay press withdrew.

Dr MIDDLETON MARTIN moved the amendment of which he had given notice at the previous sitting with regard to the duties of the whole-time medical officer of a public school. The recommendation of Council was that these duties should include "examination of all new pupils on admission to the school" and "periodical examination of resident pupils." Dr Martin's amendment was that the word "resident" should be replaced by the word "all." Dr Martin said that the object of the examinations was to detect conditions at an early stage and there was as much reason for the examination of non-resident as of resident pupils. Mentioning concrete instances he said that a young girl known to him was a day pupil at one of the large public schools and only in the course of the second examination was it found that her eyes were weak and that she needed glasses. Exactly the same thing happened with another girl at the same school. The nephew or a representative present would have taken part in a strenuous rowing race if he had not been re-examined.

Dr BONE said the committee had adopted the policy framed in the motion after very careful consideration. Some schools consisted mainly or almost entirely of resident pupils but a school might have few resident and a very large number of day pupils. The latter would be attended by their own doctors. The committee decided

that it would be quite wrong to take away from the private practitioner the duty of looking after his own patients. The point of policy involved had often been considered by the Association in other connexions and it had always decided that the private doctor should not be disturbed.

Dr MARTIN said in reply, that the committee's argument applied equally to re-examinations and examinations. The amendment did not relate to treatment. Cases of eye defect detected by the examining doctor would be referred to the usual medical attendant.

The amendment was lost by a narrow majority.

Dr COWELL (Croydon) proposed that "re-examination" be substituted for "examination" and that "keeping of medical records of resident pupils" should follow immediately, instead of appearing further down in the list of duties.

Dr BONE thought there was no sufficient reason for changing "examination" to "re-examination" and he preferred that the phrase about keeping records should remain where it was.

The amendment was lost.

Dr G. W. MILLER (Dundee) moved that the recommendation setting out the duties of the whole-time officer should be amended by the deletion of the words "dispensing of medicine, but not the provision of drugs." He said that it was fifty years since the dispensing of medicines ceased to be part of the routine duty of medical practitioners in Dundee and many other parts of Scotland. There should be no occasion for it if a qualified pharmacist was anywhere available. Medicine dispensing was in a different category. Furthermore, such dispensing was no part of the duty of an insurance practitioner.

Dr BONE replied that it was the custom in public schools for the medical officers to dispense. For the most part the schools were isolated and no qualified pharmacist was available. He saw no reason why the Association should suggest an alteration of a duty which was customary and to which none of those who were performing it raised any objection. They were not dealing with insurance practitioners.

Dr MILLER added that if a qualified dispenser was not available there was no objection to the medical officer dispensing and it was not necessary to specify it as one of his routine duties.

The amendment was lost and the recommendation setting out what the duties should include was then agreed to, as were further recommendations setting out the duties which should not be demanded and the requirement that a whole-time officer should not be allowed to enter into private practice or undertake consultative work outside the school community but that he might make certain private arrangements for attendance on masters and their families and on school servants. It was also agreed that in the case of a preparatory or junior branch school under the same governing body as the principal school it should be open to the medical officer to the principal school to act as medical officer to such preparatory or junior branch, though not to such a school which was not under the same governing body.

#### PART TIME MEDICAL OFFICERS OF PUBLIC SCHOOLS

The meeting then turned to the consideration of the part-time officer. On the motion of Dr BONE it was agreed that a part-time medical officer should be appointed by the governing body of the school. He next proposed that the usual duties of such a school medical officer should include attendance on sick resident pupils, reports to masters on such pupils, correspondence with parents with regard to the health of resident pupils, and accessibility when school games were in progress.

Dr ROXBOROUGH asked what was a public school. Did it mean Eton or Harrow? Dr BONE replied in the affirmative. Eton and Harrow were public schools. There were a good many more, of course.

The word "accessibility" was taken objection to by Dr R. W. LESLIE (Belfast), who expressed the gratitude

of part-time medical officers of public schools to the committee for their labours and efforts on behalf of a hard-  
working and worthy body of men. He said  
that the committee was not to be competent to undertake any duty which would take him out of telephonic communication with the school. He suggested the difficulty would be met by the phrase "reasonable accessibility," and this was accepted by the meeting.

Dr WALLACE HENRY pointed out that the duties of a whole-time officer included "special reports to the headmaster and house masters re patients," whereas the wording of the present motion relating to part-time officers was "reports to masters on sick resident pupils." He asked why there was a difference in the wordings, and suggested that they were intended to mean the same thing.

Dr BONE said the difference was intentional. It was considered that the duties of a part-time officer differed to a considerable extent from those of a whole-time officer, and that this was one of the ways in which they differed. In one case there was a whole-time man whose whole life was devoted to the particular job, and it was thought that the duties in the one case were, and ought to be, more elaborate than in the other. The original motions contemplated advising the Representative Body that whole-time men ought to be appointed wherever possible. It was considered that the whole-time men were an improvement on the part-time men. It was not thought right or proper to lay down the same very elaborate set of duties for the part-time medical officers as were laid down for the whole-time men.

The motion was then carried.

Dr BONE next moved a recommendation with regard to the remuneration of a part-time officer—namely, that it should be either

(a) By a capitation fee of not less than 10s 6d per resident pupil per term, or £1 11s 6d per resident pupil per year,

(b) By salary of such amount as shall be equivalent to the remuneration of the whole-time officer, or  
graph (a), or

(c) By arrangement with the parents of the pupils where the parents are directly responsible to the medical officer for the payment of his fees.

This was agreed to.

Dr BONE then moved that the duties of the part-time officer might also include

Examination of new pupils on admission to the school  
Periodical examination of pupils  
Keeping of medical records of resident pupils  
Supervision and inspection of dietary of resident pupils  
Supervision and inspection of physical training of pupils  
Simple vision and colour vision testing  
Advice on all hygienic measures in connexion with school work

Mr E W G MASTERMAN asked why there had been an objection to Dr Martin's motion, and yet here the part-time officers were to make periodical examinations of pupils.

Dr F W GOODBODY (Manselton) said one reason for the alteration in the wording between the previous motion and the present was that the committee had had the advantage of the counsel of two members of the Association who were doing part-time work at schools. Their duties were very different, and they had pointed out that some schools preferred the medical officer to examine all pupils, and some only resident pupils, but that in several cases, like Eton, where there were half a dozen doctors concerned with the treatment of the boys, the customs among those doctors varied very much. Some thought they should examine, and some thought they should not examine. That was why the word "resident" was left out in the present motion.

Dr D McKIN (Glasgow Eastern) moved as an amendment the insertion of the word "resident" so that the second line in the list of duties would read "Periodical examination of resident pupils."

Dr J A MACDONALD seconded the amendment.

Dr DAVID CLOW (Gloucestershire) supported the recommendation of the Council as it stood. The present afforded

a unique opportunity for the investigation of the normal. The proper study of disease should begin with the investigation of the normal. Valuable work had been done in the last few years in this connexion. If the work was spread among several medical officers, no doubt the scheme could be followed by them, but the same attention would not be given by the man outside—to whom the work was not part of his day's work, as it were—as would be given by the medical officer whose special interest it was to examine the pupils. He would like to see it adopted as the policy of the Association that all pupils should be examined and re-examined by the same medical officer.

Mr BISHOP HARRIS supported the recommendation as it stood. In the interests of the pupils it was far better that the examination should be as wide as possible. He had yet to learn that in the elementary schools there was the least difficulty in the matter.

Dr H S BEADLES considered that the word "resident" should be inserted, and Dr EUSTACE HILL (Public Health Service) opposed the insertion.

Dr BONE left it to the meeting to say whether or not the word should be inserted. He was quite prepared to accept the amendment.

The amendment was carried, as was also the recommendation as amended.

Dr BONE further moved

That where the additional duties enumerated in the foregoing recommendation are required of a part-time medical officer of a public school the remuneration should be increased by higher capitation rate or retainer fee.

The motion was carried.

The final recommendation repeated what had already been agreed to in the case of the whole-time officers, that satisfactory arrangements should be made in school curricula for giving instruction to the pupils on questions of health and hygiene. It was adopted without further discussion.

The minutes of the proceedings in committee were read to the committee by the MEDICAL SECRETARY, and were confirmed.

#### PROCEDURE ON THE PUBLIC SCHOOL RESOLUTIONS

##### Resumption of Plenary Session

Dr BONE moved that the committee of the Representative Body report to the Representative Body that it approved of the amended resolutions on the position, duties, and salaries of public school medical officers proposed by the Council.

This was agreed to, and the Representative Body then resumed its normal session. After Dr BONE had moved that the report of the committee (as above) be adopted, Dr MIDDLETON MARTIN desired to move again, as he was entitled to do under the rules of procedure, the amendment he had moved in committee, which had then been lost, but he now modified it so that it became a reference to Council to consider whether the word "all" should not be substituted for the word "resident" in the statement as to one of the duties to be expected of the whole-time medical officer—"periodical examination of all pupils"—not merely resident pupils—but he added that an exception should be made where a certificate from the pupil's private attendant was presented.

The vote on this amendment was so close that it had to be recounted. The final figures were

For the amendment	81
Against	80

The report of the representatives in committee to the Representative Body was then approved, with the request that the Council should consider what had just been embodied in the amendment.

Dr WALLACE HENRY moved that it be an instruction to the Council to enter into communication with the governing bodies of public schools on the position, duties, and remuneration of their medical officers, in accordance with the recommendations of the Council as amended, which had been approved by the Representative Body in committee. He said they had given the chairman of the Medical-Political Committee the backing he desired, but they had not yet made the resolutions which had been proposed.

forward the policy of the Association because they had not been formally approved by the Representative Body in session. Several members were anxious that the Association should not, as it were, hold a pistol to the heads of governing bodies or public schools. Now the Association would be able to approach them and discuss in a friendly way the general views that had been adopted.

Dr PETER McDONALD seconded the resolution.

Mr McINAM ECCLES Does that include conference with the Headmasters' Association?

The CHAIRMAN If they are willing to have one.

Dr WALLACE HENRY had no objection to the suggested addition.

The CHAIRMAN We must not forget the headmistresses.

It was agreed that the resolution read "governing bodies of public schools and other bodies concerned."

The resolution was carried.

#### Periodic Physical Examination of Pupils

Dr E. K. LE FLEMING moved on the remainder of the Report.

That the Representative Body is emphatically of opinion that provision for periodical examination of and report on the physical development of pupils at public schools should be established by every such school.

He thought it would be unfortunate if they did not take this the first opportunity they had had to emphasize the need for the periodical examination of all pupils. Every medical officer associated with a public school knew that large numbers of boys and girls suffered from all kinds of physical defects that were allowed to pass unnoticed until they brought about a complete breakdown in the pupil as a scholar. Parents seemed to assume that it was logical to pay a large sum of money for the mental education of their children and that the physical side of their development should proceed on perfectly normal lines and require no attention. They were very much to blame in that respect. The school was the place where children could be safeguarded from developing physical defects by attention at an early stage, and it was practically only at public schools that this necessity was not recognized. In the forefront of its policy the Association should emphasize the necessity for the periodical examination of pupils.

Dr JOHN-ON SMITH seconded the resolution.

Dr BOYE said that the Medico-Political Committee recognized the very great need for the periodical examination of all pupils. It was of vital importance that boys and girls at the age of growth and development should be examined and re-examined, so that at the earliest possible moment signs of physical disease could be detected and vigorous exercises adjusted accordingly. He agreed with everything Dr Le Fleming had said.

Mr BISHOP HANMAN said they were asking that the immense benefit that children in elementary schools had derived from periodic examinations by medical officers should be extended to pupils in public schools. He was often shocked to find that defects that had been present for many years had not been discovered in the family or the school until some unfortunate incident arose out of it.

The resolution was carried without dissent.

(To be continued)

### ANNUAL GENERAL MEETING

THE ninety-fifth Annual General Meeting of the British Medical Association took place in the McWan Hall of Edinburgh University on Tuesday July 19th 1927 at 2 p.m. The PRESIDENT (Mr Robert G. Hogarth, C.B.E.) was in the chair.

The Notice convening the meeting was read by the FINANCIAL SECRETARY and the Minutes of the Annual General Meeting held in Nottingham on July 20th 1926, which had appeared in the SUPPLEMENT were taken as read and confirmed.

#### INDUCTION OF PRESIDENT 1927-28

Mr HOGARTH then inducted as President, 1927-28, Sir Robert W. Philip, M.A., M.D. F.R.C.P. L.D., Hon. F.R.C.S. Ed. Honorary Physician to the King in Scotland, professor of tuberculosis in the University of

Edinburgh, physician consultant, Royal Infirmary, Edinburgh, and invested him with the presidential badge of office. After doing so, he said that it was a good rule that formal speeches should be brief, and that he did not intend to break the rule, but even the briefest utterance might be aglow with warmth, and as he now vacated the presidency and invited his successor to take it from him, he wished to offer his most cordial congratulations to one who had added new lustre to a city long famed throughout the wide world for the learning, for the skill and for the character of its medical men (Applause). He could not hope to tell the medical profession in Edinburgh anything that was not already known about Sir Robert Philip and his brilliant work. It would also ill become him to praise one whose great merits had received such general and such signal recognition. He hoped that Sir Robert would enjoy his year of office as much as he (the speaker) had enjoyed his own. He was sure that at its close Sir Robert would agree that there was no office that fell to a doctor's lot which was more honourable or more desirable than that of the presidency of the British Medical Association.

The PRESIDENT said that to succeed to the long list of distinguished men who had been Presidents of that mighty Association was a significant event. That was not the moment for him to say very much. He would have an opportunity later on of expressing at greater length his appreciation of the high honour to which the members, in their goodness, had called him. The present was a very proud moment in his life but it was one at which he felt weighted with a sense of responsibility. He begged the members to receive his sincere and respectful thanks for a fresh expression of their kind confidence (Applause).

#### APPOINTMENT OF AUDITORS

Dr E. A. STAMMING proposed that Messrs Price, Waterhouse, and Co. be appointed auditors to the British Medical Association until the next Annual General Meeting, at a remuneration of 200 guineas.

Dr MIDDLETON MARTIN seconded, and this was carried unanimously.

#### PRESIDENT ELECT

The CHAIRMAN of the REPRESENTATIVE BODY (Dr Brackenbury) reported to the meeting that Sir Ewen Maclean M.D., F.R.C.P., F.R.S.E., senior gynaecologist, Cardiff Infirmary, had been elected by the Representative Body as President of the Association for the year 1928-29.

Sir EWEN MACLEAN said that he was grateful for a further opportunity of expressing his very warm thanks for the high honour which had been conferred upon him. It was especially gratifying to him that it should have come in the city or his old and much loved alma mater an institution which enshrined within her walls all the lasting affection of her sons and daughters. It would be a very difficult thing for him to follow in the footsteps of one with the personal charm and the high distinction of Sir Robert Philip and difficult also to follow in the wake—the fading wake—of their friend Mr Hogarth who had done such faithful work for the Association in the past year. It would not be easy for Cardiff to follow Edinburgh with all her great traditions and achievements, but there were attractions in the Principality, and it only remained for him to assure the Association, on behalf of the profession in Wales North and South together with the civic and collegiate authorities, that they would do their best to give the Association a warm Welsh welcome (Applause).

#### NOTE OF THANKS TO PAST-PRESIDENT

The CHAIRMAN of COUNCIL (Sir Robert Bolam) proposed that the hearty thanks of the Annual General Meeting be given to the retiring President, Mr R. G. Hogarth, for his services as President 1926-27. He said that of the various Presidents he had encountered as an executive officer of the Association during the past seven years none had been quite so unexpected as Mr Hogarth (Laughter). Throughout the term of his office, as titular head of the Association, in his public appearances, in his address at Nottingham—(applause)—which deserved and received universal commendation and notice, and in his subsequent public appearances during a year in which there had been

many functions and ceremonies, he had done work of the very greatest value in forwarding the interests of the profession and the Association (Applause)

The new President (Sir Robert Philip), adding a personal expression of gratitude, said that during the past year he had been in a kind of helpless chrysalis stage, of rest, insensibility, and inactivity, and Mr Hogarth had been like a master gardener, indicating what might come in the future, and tending him as a father or elder brother.

Mr HOGARTH said that if his year of office had been of service to the British Medical Association he should feel far more than repaid for its cares. He had received such cordial and unsparring assistance on every side, especially from the permanent officials of the Association, that what might have been a burden had been so lightened as to be almost unfelt. Friendly hands and faces had made the way easy for him over the whole course. The well-being and advancement of the British Medical Association and the strengthening of its effectual influence in the great part it played in the medical profession would always command his active sympathy and the best that he had to give.

The Meeting then adjourned until the evening

### ADJOURNED ANNUAL GENERAL MEETING

THE adjourned Annual General Meeting was held at 8 o'clock in the Usher Hall, Lothian Road, Edinburgh. The spacious hall, with its two galleries, was filled in almost every part when Sir ROBERT PHILIP, President of the Association, took the chair. He was accompanied on the platform by Lord Sands, Sir Alfred Ewing (Principal and Vice-Chancellor, Edinburgh University), Professor George M. Robertson, P.R.C.P. Ed., the Right Rev. Dr. Norman Maclean, the Very Rev. W. P. Paterson, Sir David Wallace, Dr. Drummond Shiels, M.P., Sir Leslie Mackenzie, and many other representatives of the civic and university life of Edinburgh and of Scotland.

Others more closely identified with Association activities also on the platform were Mr. R. G. Hogarth (Past President), Sir Fwen Maclean (President-Elect), Sir David Drummond (a former President), Dr. C. O. Hawthorne (Chairman of the Representative Body), Dr. H. B. Brackenbury (Past Chairman), Sir Robert Bolam (Chairman of Council), Mr. Bishop Hamman (Treasurer), Dr. J. A. MacDonald, Sir Jenner Verrall, Sir William Macpherson, and many other members of Council.

### INTRODUCTIONS

Sir ROBERT BOLAM opened the proceedings by asking Dr. Feigus Hewat, the honorary local general secretary, to present to the President a large number of delegates from kindred associations, foreign guests, and representatives and delegates from Overseer Dominions. Each of these visitors received a greeting from the audience, in some cases, particularly that of Professor Harvey Cushing, a specially cordial one.

The following were the delegates presented from kindred associations:

*Canadian Medical Association* Dr. H. S. Bukett, Dr. J. T. Lotheringham, Dr. James Miller, Dr. F. N. G. Starr  
*American Medical Association* Dr. G. H. Simmons (Editor Emeritus), Dr. W. S. Thayer (President Elect)  
*China Medical Association* Mr. Dugald Christie

The following were the foreign guests:

*Denmark* Professor Knud Leber  
*France* Dr. P. F. Aimand Delille, Professor L. Blum, Professor R. Cruchet, Professor Georges Guillaum, Dr. E. Rist, Dr. René Tugowla  
*Germany* Professor Gustav Embden, Dr. E. Martini  
*Holland* Professor Jan van der Hoeve, Professor E. C. van Leeuwen  
*Hungary* Professor Emile de Grosz  
*Italy* Professor Vittorio Ascoli  
*Sweden* Professor K. A. Petron  
*Switzerland* Professor F. R. Nager  
*United States* Professor Harvey Cushing, Dr. Theodore Diller, Professor E. L. Opie

The representatives and delegates from Overseer Dominions presented were as follows:

Dr. F. E. Whitehead (Nyasaland), Dr. T. D. Greenless (Cape Eastern and Orange Free State and Basutoland), Dr. J. I. Rubidge (Cape Midland), Mr. T. Lindsay Sunda (Cape Western), Dr. Spencer Wicks (Griqualand West), Mr. G. V. Huggins (Natal), Dr. J. J. Boyd and Dr. A. G. (Pretoria), Dr. W. T. F. Davies, Mr. Max Greenberg, and Mr. H. Temple Munsell (Witwatersrand).

Dr. W. H. Percock (Sierra Leone)  
Dr. Sinclair Gillies, Dr. W. L. Kirkwood, and Mr. E. T. Thing (N.S.W.), Dr. C. E. A. Coldicutt, Dr. A. Donohue, and Dr. W. Young (New Zealand), Mr. E. A. Lahan (Queensland), Dr. L. J. Balfour, Professor R. J. A. Berry, Dr. B. Stewart Cowen, Dr. Konrad Hiller, Dr. L. S. Latham, Dr. Felix H. Meyer, Dr. J. H. Nuttall, Dr. J. E. Nicholl, and Dr. T. W. Sinclair (Victoria), Dr. A. W. Farmer (Western Australia).

Dr. S. Segun Strahin (Hong Kong and China)  
Mr. F. C. Madden (Egyptian)  
Dr. S. P. Kapadia (Bombay), Dr. L. D. Parsons and Dr. Lucian de Zilva (Ceylon), Major M. G. Naidu (Hyderabad), Lieut. Colonel R. E. Wright, I.M.S. (South Indian and Madras).

The Hon. Sir David J. Galloway (Malaya)  
Dr. W. Dunlop (Mesopotamia)  
Dr. E. H. Bannister (Barbados), Dr. Q. B. de Freitas (British Guiana).

A cablegram was read from Dr. Orenstein of Johannesburg conveying, on behalf of several councils and professions of South Africa, best wishes to the Annual Meeting.

### THE SIR CHARLES HASTINGS CLINICAL PRIZE

The CHAIRMAN OF COUNCIL said that the Sir Charles Hastings Prize was a clinical prize which had been instituted to encourage systematic observation, research, and record in general practice. This year it had been obtained by one who, practising in Lancashire, had been a worker for the British Medical Association in medico-political circles. Dr. J. S. Manson had sent in an essay of extraordinary merit and had been awarded what was regarded as one of the prizes of the general practitioner the Sir Charles Hastings clinical prize.

The PRESIDENT, in presenting the prize, which consisted of an illuminated certificate and a cheque for fifty guineas to John Sinclair Munson, M.D., Warrington, for his clinical study entitled "Observations on human behaviour," said: "On behalf of the British Medical Association I have very great pleasure in awarding you this prize, and at the same time congratulating you on having found, in the midst of your ordinary daily work, opportunity for such able observation."

### PRESIDENT'S ADDRESS

The PRESIDENT then delivered from the chair the address which is printed at page 123.

### VOTE OF THANKS TO THE PRESIDENT

At the close of the presidential address, which was received with long-continued applause, Dr. C. O. Hawthorne (Chairman of the Representative Body) proposed a vote of thanks to the President. He said that to praise Sir Robert Philip in Edinburgh was of all things a superfluous proceeding, and to commend him and his distinction and his work to his colleagues in the medical profession was equally unnecessary. In the British Medical Association it was considered scarcely to leave the presidential address for careful study and contemplative reflection, and thus it did not fall upon him (Dr. Hawthorne) to undertake the formidable task of analysis or comment. It was sufficient to say that the scientific value of the address, its economic implications, and its bold advent into the field of optimistic prophecy would all receive the most careful consideration, while its literary charm would appeal to every reader, even as it had to those who had been fortunate enough to listen to its delivery. In Edinburgh medicine was cultivated with a structure of philosophy and this address strikingly illustrated the truth of the proposition (Applause).

Sir ALFRED EWING (Principal and Vice-Chancellor of the University of Edinburgh), in seconding the vote of thanks, said there could be no two opinions as to the suitability

of their choice of a President nor as to the distinction, the literary charm, the philosophic grasp, and the immense suggestiveness of the address they had just heard. As a layman he had been brought into intimate contact with Sir Robert Philip in matters of administrative detail regarding the University, details sometimes medical, sometimes non-medical, and there was no occasion when Sir Robert Philip's opinion had not been of the greatest value. Sir Alfred Ling did not remember ever to have seen the President's serenity ruffled or his judgement other than calm and balanced. The tremendous work which Sir Robert Philip had described that night illustrated a striking characteristic of the profession—that it had achieved its own greatness by its humanity.

The vote of thanks was heartily accorded, and Sir ROBERT PHILIP briefly expressed his thanks and asked his hearers to meet him a little later at the reception by himself and the local executive, at the McEwan Hall.

### OPENING OF THE ANNUAL EXHIBITION

THERE was a strong muster of members of the Association and visitors in Waverley Market Hall, Princes Street, on Tuesday morning for the official opening of the exhibition of surgical instruments, appliances, drugs, foods, etc. Dr BRACKENBURY, Chairman of the Representative Body, presided, and others present on the improvised platform were Sir Robert Philip, Sir Ewen Mackenzie and Sir Robert Bolam, Chairman of Council.

Dr BRACKENBURY said that the British Medical Association always desired to give as much publicity as it could to the Exhibition, and, following a very advantageous custom, he would ask the President-Elect who would become President in the course of that meeting, to commend the Exhibition and declare it open.

Sir ROBERT PHILIP said:

The Chairman has just told us that it is a happy custom that the President-Elect should declare this Exhibition open. I am not quite sure that it is quite a satisfactory custom so far as the Exhibition is concerned, but for this I am certain that no duty could be more grateful, more acceptable to the man who occupies the position I do for the moment than the opening of this Exhibition. Looking round and knowing the Waverley Market as I do, I feel that there has been a transformation or a somewhat dubious building into a world of beauty. (Hear, hear.) That world of beauty is not everything that we see for the moment from this platform because as you pass from stall to stall revelations emerge of a most astonishing and interesting character. This Exhibition I take it, stands for the union of brain or thought, the vision of the doctor, the experimenter, the man who is feeling his way and the ingenuity of the technician without which mirror you all our fine thoughts would carry us a very short distance. The medical profession owes a great deal to our fellow-workers whether they are the manufacturing chemists, the pharmacists, the scientific instrument makers, or the publishers and I desire as getting to be an oldish member in the profession here and now to express to all the representatives all these fellow-workers our sense of this indebtedness. (Applause.) It is particularly significant to realize that happy union in this city because in Edinburgh during the past centuries there have been two very notable examples of the value of the combination to which I have alluded. In the first place in the earlier time not very far separated the one from the other you had Sir James Simpson feeling his way following the example of men in America and elsewhere to realize the great principle and practice of anaesthesia. Sir James Simpson in all his observations was assisted—more than assisted, notably assisted—by his association with a leading firm of chemists in the city of Edinburgh. (Hear, hear.) Then, coming to another point in history which is very much in our minds just now when we are out to commemorate the life of that great man Lord Lister, it must be known to many Edinburgh men here how very closely related—I was going to say how dependent—Lord Lister was and he would have been the first to have expressed this view himself on his association with fellow-workers on the technical side. The firm of Messrs. Macfarlan in Edinburgh, an old historic firm, were in most intimate touch with Lister

at every point in the development of his technique, more particularly his technique in relation to the refinement of catgut and so on. On the other side of his work, another firm of instrument makers Messrs. Gardner, were closely associated with him in relation to the technique shall I call it or the old-fashioned sprag—the technique or his delicate apparatus. I am very happy that it should have fallen to me in this city, not merely to refer to the old associations, and to the gratitude that those great men who have since left us would have felt, but in the widest way once more to express the feeling of the profession towards our colleagues the technicians, and of the general public in the will allow me to say so to those men without whom the work of us doctors however desirous we might be of relieving others, might fail in its attainment. I have very much pleasure in now formally declaring this Exhibition open. (Loud applause.)

Dr BRACKENBURY said it was very gratifying to see so large an assembly, and on behalf of the exhibitors, the members of the British Medical Association and members of the public he thanked Sir Robert Philip, not merely for declaring the Exhibition open but for his charming, illuminating, and enlightening address. (Applause.)

### THE REPRESENTATIVES' DINNER

At the conclusion of the first day of the Annual Representative Meeting the representatives dined together in the debating hall of the University Union. Unfortunately Dr Brackenbury, soon after his arrival to preside over the dinner, was seized with indisposition and his place in the chair was taken by Dr C. O. Hawthorne. The shadow which the temporary illness of Dr Brackenbury cast upon the assembly was in part dissipated later in the evening when the CHAIRMAN of COUNCIL announced that Dr Brackenbury, who had returned to his hotel, was very much better.

Dr E. J. TOYE of Barnstaple who had been selected to propose the toast of Chairman of the Representative Body, found himself as he said, taking part in a performance of *Hamlet* without the Prince. But he proceeded with the speech he had prepared which dwelt upon Dr Brackenbury's name, qualifications, and offices, and even extracted some oratorical capital out of his telephone number! Dr Brackenbury, he said, derived thoroughly well of the medical profession and the British Medical Association, in whose interests he had laboured with such ability and devotion.

The toast to the absent Chairman was pledged with great heartiness, and to the singing of "For he's a jolly good fellow."

Dr HAWTHORNE took advantage of the occasion to apply some familiar quotations to Dr Brackenbury among them that passage of Scripture concerning the one who waxed valiant in fight, put to flight the armies of the alien, stopped the mouths of lions—and sometimes of other members of the animal kingdom who had nothing of the lion about them except the skin! Dr Hawthorne also referred to some of the lighter sides of the Representative Meeting, its relaxations and hesitations and pointed his remarks with some timely illustrations of the more delicate sides of the relationship of host and guest. He concluded by expressing the regret of all those present that at that particular moment Dr Brackenbury after his labours as chairman, should have been prevented by what they all hoped was only a passing indisposition from spending an agreeable evening among his friends.

Professor LOVELL GULLAND related some reminiscences of the visit of the Association to Edinburgh in 1893 when Sir Thomas Granger Stewart was President and Sir Robert Philip Honorary Secretary and he obliged the company with a song specially composed for the occasion nearly thirty years ago. In these days, he said, the local people had nothing like the help they now enjoyed from headquarters but they got a great deal of fun out of the meeting and put in an immense amount of hard work. The song which was of many verses included one which ran:

We chose the committees with thought and with care  
With infinite constabulation  
While the Sections were picked so that all had a share  
And none could complain of the Association

The lines also bewailed the ease of

Poor Philip who had the life of a dog,  
His days were a long tribulation,

while

Sir Thomas who acted the President's part,  
Is deserving of high commendation

Further poetic gifts were revealed by Dr WILLIAM FORDYCE, who gave a recitation of many verses, the theme of which was a rather remarkable (and, to those who know him, unbelievable) episode in the career of Sir Harold Stiles, but as the poem concluded by stating that it was all a dream it need not be taken too seriously. The recitation was delivered with much dramatic vigour, and received immense applause.

The company broke up after singing 'Auld Lang Syne'. The attendance was very large, and the Chairman was supported by the President, Mr R G Hogarth, and the President Elect, Sir Robert Philip.

## THE REPRESENTATIVES' EXCURSION

### A VISIT TO THE SCOTT COUNTRY

ON Sunday the representatives and their wives spent a delightful day in the Scott country, more than 500 of them journeying by car and charabanc to the Border. The weather was everything that could be desired.

The party started from the Royal College of Physicians at 9.30 a.m., and proceeded to Rullion Green, where a most impressive service was conducted by the Revs I Ratcliffe Barnett and George F Macleod. On the actual site of the old Covenanters' battlefield, in a dip in the hillside, a short and interesting address was delivered, in the course of which it was pointed out that some 250 years ago a band of 900 Covenanters, from Dumfriesshire, half starved and badly armed, took their stand. Their homes had been destroyed and they were endeavouring to reach Edinburgh. At Rullion Green they were attacked by 3,000 well armed Government troops under Dalziel of Binns. Retreating south, the Covenanters took up a position on the actual spot where the service was held. On Dalziel's first attack he was routed, but a later attack in the evening ended in the defeat and flight of the Covenanters. The dead and wounded were left lying in the snow (the battle was fought on November 8th, 1666), and were stripped and robbed. In the night the godly women of Edinburgh came out and clothed the naked dead in white shrouds. They were buried on the battlefield, where a monument has been erected to commemorate their heroism. About 150 prisoners were taken to Edinburgh, and either put to death or shipped to the plantations. So ended one of the most celebrated battles of 'the Killing Time,' during which over 15,000 Covenanters perished in support of the Presbyterian form of worship. The minister claimed that, largely as the result of the magnificent action of the Covenanters, freedom of thought in religion had been secured in Scotland for all time.

The representatives then proceeded to Penmonk, Peebles, and Gilshields. Here an excellent lunch was served. The Provost showed the party the beautiful war memorial of the town. Of a population of some 15,000, over 3,000 had proceeded overseas during the great war, and of these some 600 had given their lives for their country. After passing Abbotsford, the later home of Sir Walter Scott, the ruins of Melrose Abbey, beneath the slope of the Eildon Hills, were seen. Here, in the remains of the Abbey, founded in 1136, and endowed by David I for the Cistercian Order, near the eastern end, is buried the heart of Robert Bruce, many border chieftains, including Michael Scott, the Wizard, lie here.

Bemerside House was passed—the house presented by the nation to Field Marshal Earl Haig as a tribute to his services in the war, and which fulfilled the ancient prophecy—

"Tide—tide—white er betide  
There'll aye be a Hug in Bemerside."

During a halt at Dryburgh the visitors inspected the Abbey, founded by David I of Scotland in 1150. It was a brotherhood of Premonstratensian monks from Alnwick, and was four times destroyed by English armies. Here is buried Sir Walter Scott, his wife, and members of his family. After a drive along Tweedside Kelso was reached. There, at Floors Castle the representatives were entertained to tea by His Grace the Duke of Roxburghe. In a large marquee in the beautiful grounds of the Castle a very refreshing meal was served, after which the gardens and hot houses were inspected. The delightful weather enhanced the natural beauty of the grounds of Floors Castle, which were in perfect condition. The drive home through most glorious Border scenery terminated a very delightful and

memorable excursion, very much appreciated by the large and distinguished party, which included most of the officers, officials, and members of the Representative Body.

A slight accident occurred during the journey. A small child, through no fault of the driver, was knocked down by one of the charabancs. She was immediately examined by two distinguished surgeons who were in the vehicle. It was explained to the mother that two well known surgeons had satisfied themselves that no serious harm had overtaken the child, and that she had nothing more than a few slight bruises. The mother remarked, "Thanks, but I'll have my own doctor," a remark very much appreciated by everyone in the charabanc, and not least by the two surgeons.

## ENTERTAINMENT BY THE EDINBURGH AND LEITH DIVISION

ON Saturday evening the Edinburgh and Leith Division gave a smoking concert to the representatives in the Debutin Hall of the Union Society. Dr William Guy in the chair, and Dr Fordyce acting as deputy chairman.

Dr Guy, in a welcome to the visitors, recited with his well known sonorous eloquence the following poem, composed by himself.

All hail! you representatives from far and near  
We bid you welcome, offer you good cheer,  
Furnished your task, solved each momentous question,  
No mental strain inhibits good digestion,  
So east aside the cares of class or practice  
With thankful hearts admitting that the fact is  
Though bugs of all kinds, oecous or braillous  
Or even spirochaeta may try to kill us,  
The wise practitioner who would slay these bugs  
Puts not his trust in vaccines or in drugs,  
But rather in the microbes deadliest foe—  
Tobacco smoke + C<sub>2</sub>H<sub>5</sub>O  
To this prescription it is never wrong  
To add a dose of music and of song,  
Lift up your voices then, and swell the chorus,  
Bass, tenor, baritone, in tones sonorous!  
And if perchance the effort makes you pant,  
Restore the rhythm with a stimulant  
Of stimulants the one without a peer  
All will agree is good old British beer!  
Now must I stop and come to the agenda,  
The order of the night "Nunc est bibendum!"

The concert was a very successful one, among those contributing to the entertainment being the chairman and vice chairman and many of the students.

A great feature was some good community singing of old Scottish songs, such as "John Peel," "Billy Boy," "Loch Lomond" and well known students' verses, "What shall we do with the drunken sailor?" "Solomon Levi," "A roving," being rendered with great gusto by the large audience assembled.

Dr J A Macdonald, in a few well chosen phrases, expressed the thanks of the guests for the excellent entertainment provided, and the concert concluded with the singing by the audience, in true Scottish fashion, of "Auld Lang Syne."

As was anticipated, the number of members attending the Annual Meeting in Edinburgh is large, down to 2 p.m. on Wednesday, July 20th, 2,000 had registered their names.

## British Medical Association

### CURRENT NOTES

**Handbook for Recently Qualified Medical Practitioners**  
THE second edition of the Association's *Handbook for Recently Qualified Medical Practitioners* was issued in April of last year. The demand for this guide to the intricacies of medical practice has been so great as to necessitate a reprint, and it is evidently not confined to newly qualified, for whom the handbook was primarily intended. A special feature of the present edition is the amount of space devoted to the practical aspects of medical work, including the legal and social obligations of the practitioner. The appendices include the Warnings Notice issued by the General Medical Council, the rules of the Body of medical consultation approved by the Representative Body of the British Medical Association, and the *Prætorian* on the duties of doctors and dentists.

Dangerous Drugs Acts, 1920-23, issued by the Home Office. The handbook can be obtained on application to the Financial Secretary and Business Manager, price 3s 8½d post free. Copies are presented to newly qualified practitioners through the Divisions and Branches.

#### Medical Appointments Abroad.

The head office of the British Medical Association has a good deal of information placed at its disposal by its Branches overseas, which may be very useful to those proposing to accept medical appointments abroad. Practitioners are cordially invited to apply to the Medical Secretary, B.M.A. House, Tavistock Square, W.C.1, for any information that may be available regarding overseas appointments in which they may be interested.

#### The Half Yearly Indexes

The usual half-yearly indexes to the JOURNAL and to the SUPPLEMENT and EPITOME have been prepared and will be published shortly, they will, however, not be issued with all copies of the JOURNAL, but only to the readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this desire.

### Association Notices

#### ULSTER BRANCH NORTH EAST DIVISION

The Council has changed the name of the Ballymoney, North Antrim, and South Derry Division to "North East" Division.

### Meetings of Branches and Divisions

#### CAMBRIDGE AND HUNTINGDOY BRANCH

The eighty third annual general meeting of the Cambridge and Huntingdon Branch was held at Harston Cambridge on July 12th. The following were elected officers for the ensuing year:

President: Dr W. J. Young. President-Elect: Mr W. H. Bowen. Vice-President: Dr Robt. Ellis and Dr H. Macdwyer. Honorary Secretary: Dr G. S. Haynes.

Dr Young generously entertained fifty two members and visitors to luncheon in the village hall and afterwards delivered his presidential address entitled "Then and now in midwifery." His array of facts, eloquence and wit delighted his audience and he was warmly thanked for his hospitality and entertainment.

#### DORSET AND WEST HANTS BRANCH

The summer meeting of the Dorset and West Hants Branch was held at the Weymouth and District Hospital on July 6th. The president, Dr G. Edwards, took the chair and there were forty-one members present. Mr W. A. Merrifield read a paper on acute dilatation of the stomach and Dr A. E. Blackburn opened a discussion on disease of the urinary tract. The Weymouth members provided lunch and tea for the visitors. The Branch approved the proposal that the municipal borough of Lynton and that portion of the rural district of Lynton containing the civil parishes of Milford Hordle and Milton be transferred from the Southampton Division of the Southern Branch to the Bournemouth Division of the Dorset and West Hants Branch. A Council meeting attended by sixteen members preceded the general meeting. A letter was read from the Medical Secretary as regards candidates for election to the Branch.

#### EDINBURGH BRANCH EDINBURGH AND LEITH DIVISION

A meeting of the Division was held in the Hall of the University Union on Wednesday July 13th from 4 to 6 p.m. when the graduands in medicine were entertained and welcomed into the ranks of the profession. The Chairman of the Division presided. There were present about 150 of whom 70 were graduands. Some fifty members of the Division attended, a number of whom were accompanied by ladies.

Professor D. P. D. Walker delivered to the graduands an address which was very cordially received by them and by the members. The Chairman, Dr Walker, stated the more outstanding advantages of a membership of the Association.

During the course of the proceedings the certificate from Miss Georgina Somerville for the Association prize essay was presented by the chairman. To each graduate was given a copy of the

#### British Medical Association Handbook for Recently Qualified Medical Practitioners

An enjoyable medical programme was rendered and at its close Mr MITCHELL, F.R.S. thanked the chairman and members on behalf of the graduands.

#### METROPOLITAN COUNTIES BRANCH CITY DIVISION

A meeting of the City Division was held on July 5th at the Metropolitan Hospital when Dr T. H. G. Shore, curator of the museum of St. Bartholomew's Hospital gave a demonstration of pathological specimens. This included a specimen of adamantinoma from a girl aged 17 who on admission to hospital was paralysed and deeply comatose. The urine contained albumin, sugar, and acetone. She did not respond to insulin and at the necropsy a large tumour mostly composed of blood clot was found in the brain. Dr Shore also showed an appendix containing thirty-six small shot removed from a man who was very fond of eating rabbits.

A clinical meeting of the Division was held on July 6th at the Queen's Hospital for Children when medical cases were shown by Drs E. BELLINGHAM, SMITH, SIMON, OVER, HELL, M. MACRAE, ALICE KING and D. W. WINNICOFT. Surgical cases were shown by Messrs B. WHITCHURCH, HOWELL, L. R. BROSTER, E. CROOK, R. COLE, M. VLASTO, V. NEFIELD, N. BURGESS, Dr ELIZABETH O'FLYNN and Dr W. P. TINDAL, AINSWORTH.

Another clinical meeting was held on July 8th at the Metropolitan Hospital when Dr P. HAMILL demonstrated cases in the wards.

#### METROPOLITAN COUNTIES BRANCH HARROW DIVISION

A meeting of the Division was held on June 28th. A letter about the Dogs Protection Bill written by the secretary to members of Parliament was read together with the replies of members thereto. The question whether dental anaesthetic fees under national insurance practice enabled doctors to ask for the balance of the usual fee from the patient without incurring a penalty was answered to the doctors' advantage after inquiry at the Panel Committee. As regards fees for puerperal postnatal scheme, Dr Tait of Middlesex County Council stated the fees agreed by him with the Ministry of Health and it was resolved that the secretary should write to medical officers of health of the district as to this. The Charities Subcommittee hopes to be able to report shortly. Notice of an orthopaedic clinic at Northwood was given by Dr MAYNE. Dr BERTWISTLE gave a short lecture on the libouette radiogram in the interpretation of physical signs.

#### NORTH OF ENGLAND BRANCH TYNESIDE DIVISION

On July 3rd members of the South Shields and Tyneside Divisions had a very enjoyable golfing day at Brancepeth South Shields winning the match. At a meeting of the Tyneside Division held on July 8th, Dr C. Nelson was elected to the Ethical Committee in place of Dr J. Sparks resigned. Dr S. C. Stoner and Dr J. A. Hilop were elected to the Executive Committee in the stead of Drs J. G. Nicholson and J. Forrest resigned. It was resolved that in the opinion of the Division the funds of the National Defence Fund should be used for purposes of defence in times of emergency only and that a grant of £1,000 to the Parliamentary Fund was not advisable. It was decided to stimulate the social activity of the Division by arranging a golf meeting in September and two clinical evenings and a dinner in the winter. A vote of sympathy with Mrs. Kirkland in her recent bereavement was passed and the secretary was asked to write to her. It was decided to approach again the non-members resident in the area.

#### NORTH LINCS HIRE AND SOUTH WESTLORLAND BRANCH

##### President's Address

At the annual meeting of the North Lancashire and South Westmorland Branch to which we returned briefly on July 9th (SUPPLEMENT p. 17) Dr E. Jackson in his presidential address gave an account of the improvements in medical treatment which he had witnessed during the last fifty years. He mentioned that when he started to practise it was the custom to attend a midwifery case with no equipment other than a pair of short forceps in one pocket and a bottle of ergot in the other. He described the great strides made by surgery as the result of the application of Lister's antiseptic measure, the introduction of anaesthetics and the use of x-rays. In medicine the discovery of vaccines and serums had enabled many diseases to be attacked successfully with a great resulting reduction in the mortality. Dr Jackson's reminiscences included also the change in therapeutics which followed the elucidation of the functions of the endocrine glands and an appreciation of the benefits gained by improved methods of clinical examination and diagnosis.

#### NORTHERN COUNTIES OF SCOTLAND BRANCH CAITHNESS AND SUTHERLAND DIVISION

A meeting of the Caithness and Sutherland Division was held in Thurso on July 6th with Dr D. DUNNAN in the chair. The Secretary submitted the Annual Report of Council and the Supplementary Report and the meeting discussed matters coming before the Peppercorn Body with the deputy representative (Dr A. Asher) who had agreed to act in the unavoidable absence of Dr J. B. Simpson. The following offices were elected:

Chairman: Dr D. DUNNAN (Thurso). Vice-Chairman: Dr W. E. Johnstone (Brora). Honorary Secretary: Dr A. Asher (Thurso). Executive Committee: Dr G. A. MacDonald, Dr H. Mackay, Dr A. W. Mackie, Dr A. MacLennan and Dr J. B. Simpson. Peppercorn Body: Dr A. D. Kennedy.

[ SUPPLEMENT TO THE  
BRITISH MEDICAL JOURNAL ]

been much keener than in previous years. The secretary made an appeal to all the members to try and get in many of the 47 or so non members residing in the Divisional area. Among the social activities the Division held a dance, the annual dinner was a great success, and recently its annual golf competition was taken place for prizes presented by the church. Following the ordinary business, Professor LEON VOIGT, LL D, LL B, read an address on the conditioned response. This was followed by a tea on the invitation of the newly appointed chairman.

YORKSHIRE BRANCH HUDDERSFIELD DIVISION

**LOXESHIRE BRICK HUDDERSFIELD DIVISION**  
During the past year there have been held four meetings of the Huddersfield Division and six meetings of the Executive Committee. No special questions of local interest have been discussed during the year. In March the first British Medical Association Lecture in Huddersfield was given by Professor Miles Phillips, on some obstetrical emergencies, this was very instructive and was much appreciated by those present. The social functions have again been successful, although the dance showed a deficit of £1 15 and the picnic and golf competitions were successful. The Irving Cup was won by Dr. Dickson. The Divisional round in the competition for the Treasurer's Cup has been won by Dr. Riffin. On the social functions account there is a balance in hand of about £19, in the general fund there is a balance in hand of about £8 10s.

BOOKS ADDED TO THE LIBRARY

The following books were received by the Library of the Brit. Med. Assoc. during April and May, 1927

SOUTH WALES AND MONMOUTHSHIRE BRANCH

**SOUTH WALES AND MONMOUTHSHIRE BRANCH**  
The fifty seventh annual meeting of the South Wales and Monmouthshire Branch was held at Pontypridd on Tuesday July 5th. Members of the Council, etc. entertained to lunch by the president-elect, Dr J. Morgan Rees. The Annual Report of Council for 1926 and the financial statement were approved. The officers for the coming session were elected as follows.

Dr R. PRICHARD (Chairman), President Elect Dr J W  
Treasurer Dr D Naunton Morgan (Bridgend)  
A A Prichard and Dr A W Owen

Dr R Prichard (Cardiff) the retiring president, then treated the club and mistitled Dr Rees as president for the year 1927-28. A hearty vote of thanks was accorded Dr Prichard for the efficient manner in which he had performed the duties of his office. Dr Rees read his presidential address on Pontypridd and its cottage hospital giving, first a short history of the town and its chief features. The famous bridge, built in 1755 was considered a remarkable engineering feat for the time having a single span of 140 feet. Mention was made of the building of a road to Cardiff during the American war in 1767, of the development of the iron trade and of the manufacture of cannon for the war. In 1795 a canal was built to Cardiff. This had a rise of 600 feet between Cardiff and Merthyr with 40 locks. The administration of the town in modern times was dealt with with special reference to its clinics and cottage hospital. The operative work had increased considerably since the opening, in 1913 the number of operations being 1913-14 102 1923-24 412 the majority being abdominal. A memorial park had been opened lately and afforded facilities for the workers for games of every sort. Pontypridd also possessed the only crematorium in Wales. At the conclusion of the meeting which was well attended, Dr Rees entertained the members and their friends to tea.

SUBSEA BRANCH HASTINGS DIVISION

The annual general meeting of the Hastings Division was held at the Queens Hotel on July 5th. The following officers were appointed for 1927-28:

Chairman Mr. Charnock Smith Vice Chairman Dr. E. C. Mackay  
Honorary Secretary and Treasurer Dr. T. Reed

The Honorary Secretary in presenting his annual report noted the continued prosperity of the Division. Ten ordinary meetings had been held with an average attendance of twenty three. Many interesting papers had been read, and the discussions thereof had

## MEDICAL CONFIDENCES

### THE MINISTRY OF HEALTH REGULATIONS OVERRULED

THE medical profession is aware that the confidences of a patient to his medical adviser are not in law privileged from disclosure upon oath in the witness box, but a somewhat novel point arose at the Birmingham Assizes in the course of the hearing before Mr Justice McCordie of a wife's petition for divorce. It would appear that the husband had attended a special department of the Birmingham General Hospital in 1924, and the medical head of that department, who was first called, stated that he was not the head of the department in that year, that a number of other doctors were engaged in the work, each with his own papers, which were the doctors' own personal property, and that he (the witness) had no authority to produce the papers of other doctors. The counsel for the petitioner maintained that the doctor had been called and sworn, and was bound to give evidence and Mr Justice McCordie, whilst recognizing the doctors' loyalty to his profession said that communications of a patient to his medical adviser were not privileged from disclosure in a court of law and it is information which should be given were withheld or it documents which should be produced were not forthcoming he would enforce the law and send to prison a doctor who refused to obey the order of the court. The case was adjourned until July 18th for the production of further evidence and then Mr B. T. Rose, surgeon to the hospital, after a further protest complied with the judge's direction. Another question than that of privilege arose in this case. The judge asked counsel for the petitioner if he had considered the question whether or no a doctor was bound to disclose to the court information obtained by him whilst acting confidentially in the special treatment of a particular disease. Counsel replied that there was no such protection in spite of the terms of the special regulations governing the treatment of certain diseases which were issued by the Local Government Board to local authorities in 1916. Mr Justice McCordie then ruled as follows:

The medical profession normally was under the duty of keeping inviolate the secret knowledge that they might gain from treating their patient, and indeed might become liable to a civil action for damages if without lawful excuse the duty of confidence was broken, but in a court of law a doctor had no privilege similar to that held by a solicitor or other legal adviser, and he was not privileged from compulsory disclosures or communications, however confidential. A further point arose in the present case as to whether the doctors were in a specially privileged position owing to the fact that they were acting in a department under the control of the Ministry of Health through the local health committee. In his view there was nothing in the regulations or in any regulation he had heard of which saved a doctor from the obligation of disclosure ordered to do so by the court, all the information he might have or the facts he had gained whilst acting under regulation.

Mr Justice McCordie's ruling is very clearly expressed and he no doubt had in mind Paragraph (2) of Article II of the Venereal Diseases Regulations, issued by the Local Government Board in 1916 as follows:

All information obtained with regard to any person treated under a scheme approved in pursuance of this Article shall be regarded as confidential.

So far as we are aware this paragraph has not been varied by the Ministry of Health and has been taken by the medical profession, and no doubt by patients in what appeared to be its plain sense. And that this was the sense in which the Local Government Board intended it to be taken would appear from the following paragraph in a circular issued by it with the Regulations:

By Article II (2) of the Regulations all information obtained in regard to any person treated under a scheme approved in pursuance of the Regulations must be regarded as confidential and it is essential for the success of any measures designed to deal with venereal diseases that patients should be fully assured as to the secrecy of the arrangements.

Meanwhile Mr Justice McCordie's ruling stands. In it we appear to have another instance of the uncertainty which surrounds the effect of a departmental regulation—especially when it happens to clash with an accepted rule of law. It would seem that the only way in which the Ministry of Health can implement its promise of secrecy to patients attending venereal disease centres will be by direct legislation stating in clear terms that communications by patients are protected from disclosure in a court of law.

## National Insurance

### INCREASED CLAIMS FOR SICKNESS BENEFIT

At the Scottish Conference of Approved and Friendly Societies, held on June 25th in the Central Hall, Glasgow, Mr E. Forrester, in his presidential address, referred to the serious effects produced on all societies by last year's coal dispute owing to reduced contributions and increased claims for benefit. After making due allowance for the effects of under-nourishment and worry brought about by unemployment, he thought there was still a large percentage due to a certain slackness in medical certification. Although no general charge could be made against the medical profession, he thought that a number of doctors were not exercising the care which they generally showed. A Joint Dental Benefit Committee had been set up by the Ministry of Health to consider the demands of the dental profession for increased payment, which societies were not willing to grant. The scale of fees, now known as the 1926 scale, was drawn up by the Joint Committee, and the Ministry of Health had done its best to impose this scale on societies by offering to allow any society which could not pay on this scale to contribute only 75 per cent of the treatment. At a later stage in the proceedings the conference resolved that the adequacy of the scale or charges for dental treatment be reaffirmed. Among the other resolutions passed was one requesting the Board of Health to enforce more rigidly the rules for medical certification. Sir James Leishman, in the course of an address to the conference, remarked that in the first four months of 1926 the contribution income of many societies had decreased, while the actual claims in Scotland had gone up £81,000, as compared with those for the same period in 1925. He feared that the next valuation would not show the same highly satisfactory result. The Scottish income for the previous year had been nearly four million sterling, and the payments had been almost as much. The last valuation had shown that the funds invested by or on behalf of approved societies amounted to about 13½ million sterling, a result which proved conclusively the stability, solidity, and solvency of the Scottish societies.

## Naval and Military Appointments

### ROYAL NAVAL MEDICAL SERVICE.

Surgeon Lieutenant Commanders to be Surgeon Commanders J. F. I. Campbell and R. Lyon.  
Surgeon Lieutenant Commander E. G. Adams to the Pembroke for R. Hospital Chatham on relief.

### ROYAL NAVAL VOLUNTEER RESERVE.

Probationary Surgeon Sublieutenant D. R. Goodfellow to the Clampton to complete training.  
Surgeon Lieutenants F. J. D. Allen to the Victory for R.N. Hospital Haslar for fourteen days training. W. Cathness to the Victory for fourteen days training. J. E. Purves to the Victory for R.N. Hospital Haslar additional or twenty-eight days training. R. Hall to the Victory for R.N. Hospital Haslar for fourteen days training.  
Surgeon Lieutenant Commander W. F. W. Benson transferred from L. H. to L. T. J. B. of Division.

### ROYAL ARMY MEDICAL CORPS.

Captain F. R. S. Shaw M.C. to be Major.  
The following Captains to be Majors (pro) J. H. Bayley M.C. with precedence next below R. R. Thompson M.C. W. J. Rowe, com.  
R. J. Monahan to be temporary Lieutenant.  
Captain H. D. L. E. range O.B.E. half pay. Late R.A.M.C. on completion of a period of five years on the half pay list retires on retired pay on account of ill health.

### ROYAL AIR FORCE MEDICAL SERVICE.

J. Hill is granted a short service commission as a Flying Officer for three years on the active list with effect from June 27th 1927 and with seniority of June 27th 1925.  
D. Loebelin (late Captain R.A.M.C. S.R.) is granted a short service

**CIVIL & FACTORY SURGEON.**—The following vacant appointments are announced: Bredo (Northamptonshire) Okehampton (Devon) Inthorpe (Salop) Tunbridge Wells (Kent) Applications to the Chief Inspector of Factories, Home Office Whitehall S.W.1

*This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.*

## APPOINTMENTS

BLACKSTOCK, W. P. M.B. Ch.B. Glas. Certifying Factory Surgeon for the  
Coltongham District, co. Northampton

CLIVEN, B. J., M.B., B.S. Lond. Anaesthetist to Charing Cross Hospital

## British Medical Association: Annual Meeting, Edinburgh, 1927.

### ANNUAL REPRESENTATIVE MEETING

Monday, July 1st

#### MEDICO-POLITICAL (continued)

Dr J W BONE (Chairman of the Medico-Political Committee) in moving general approval of the Annual Report of Council under 'Medico-Political' called attention to the Association's very successful action in connection with the Coroners Amendment Act. Most of those present must already have had practical experience of the very substantial increase in fees which the Association had obtained. Previously they had been working on fees laid down about forty years ago.

#### The Midwives Act 1918

Dr M W RISTON (Dartford) moved

That it be an instruction to the Council to consider the Midwives Act 1918 in the interests of all concerned in ante-natal work.

That work he said ought to be well ventilated at the Representative Meeting. Enough attention had not been given to it. Putting the parties concerned in ante-natal work in the order of their importance—the unborn child, the expectant mother, the general practitioner, the midwife—he said the first had no opportunity of saying anything and the last even opportunity of saying a great deal all day long. He agreed with Dr Martin that if the general practitioner made himself efficient he had the solution of ante-natal work in his own hands. He believed he had done that, and was well qualified in

many of the minor specialisms so predominant to-day, but he was barred and passed over in favour of the medical official. In his own area the question was an active one. Medical officers were doing clinic work and the general practitioner was not allowed to approach the clinics or the mothers in them while midwives were being trained with a rapid intensive three-days course to undertake the whole of the ante-natal work. Their country medical officer was not unsympathetic with their difficulties but he had said that it was impossible for him to do anything as the Midwives Act stood and that it required amendment before the general practitioner could be fully recognized, while meantime he must go on training midwives and allow medical officers to do the work in the clinics. He (the speaker) hoped the younger men in the Representative Body whose future would be much identified with that work would ventilate their opinions and convince the Council that it would be behind the times if it did not deal with the matter. It was not right to say that the general practitioner could not undertake the whole or the work. In his area in close co-operation with certificated midwives in a maternity hospital they got practically 100 per cent of successes and nothing like that out of de

Dr H M RAYN (Thames) seconded the motion.

Sir EWEN MACLEAN was very glad of the opportunity of commenting on what he regarded as one of the most important references of the Representative Body to the Council. By common consent ante-natal work was the

principal avenue to the betterment of maternity mortality and morbidity. The matter should be plainly faced. The principal people who had it in their hands were the general practitioners, and he thought that would continue to be the case, notwithstanding other developments in the direction of setting up ante-natal clinics or further advance in the education and experience of midwives. His personal investigations showed that general practitioners were not only willing but anxious to take part under the best possible circumstances in that life-saving work. As chairman of the Welsh Consultative Council, he visited eight or nine different centres and conferred with all the bodies and people concerned in the matter. In no centre was any element in the situation more alive or keen to undertake any responsibility in order to secure this end than was the general practitioner. A good deal would depend upon the response which the representatives made to the appeal the Council would make to them in due course, not only individually to do what they could in regard to making efficient returns which might be asked of them by headquarters, but also to use all their efforts to influence their colleagues in each of their centres to do something in this way. He desired to say, as chairman of the Puerperal Morbidity and Mortality Committee, that returns had been received from some Divisions which contained statements and facts of the highest possible value. Other Divisions had said they could not afford any information, and the committee had had to be content, in the case of far too many areas in the country, with mere washings and sittings. He begged the representatives to use their influence in regard to that matter in the future. He did not know what the Council would do with the reference, but in due course it might be his duty to point out that there was in existence a duly constituted Puerperal Morbidity and Mortality Committee. Some had suggested that that committee was dead. It was not dead, it was not even hibernating. It was gestating, and in due course it would spontaneously produce something worthy of the Association. He strongly supported the motion.

Dr D. ROBERTS also supported the motion, from the point of view of the efficiency of the man in general practice. No greater mistake could be made, he said, than to separate the general practitioner from any part of the clinical work with which he might have to do. If the attitude of some members, who were agitating for ante-natal clinics was generally adopted, then the man in general practice would be separated from the work. That was the point he desired to emphasize.

Dr BOVE said that everyone present believed in ante-natal work. The problem was a practical medico-political one, how could the general practitioner be got to do ante-natal work? That was a difficult problem, and it had to be solved through the Association's committees and sub-committees eventually. He put it to those areas in which an interest was being taken in the subject that they should send up some of their energetic men to the subcommittees. The points with regard to all these new forms of work were: How far were they to be allowed to get into the hands of whole-time officers and midwives? How far were they to come under the regis of the county medical officer of health, and so on, and how far were they to be kept in the hands of practitioners? Those were the practical problems which the committees had to solve. They could not be discussed in a big meeting such as the present. He agreed to take over the reference.

The motion was carried.

#### *Puerperal Pyrexia Regulations*

Dr W. A. M. SWAN (St Pancras), on the reference in the Annual Report to the inadvisability of laying down a uniform fee for services of consultants rendered under the Puerperal Fever and Puerperal Pyrexia Regulations, moved

- (1) That the minimum fee payable to a recognized obstetric specialist for each consultation under the puerperal pyrexia scheme be £3 3s. (excluding operative treatment), with reasonable additions for mileage to be mutually arranged with the local authorities,

- (2) That the Representative Body is of opinion that the local authority should be empowered by the Ministry of Health to pay a reasonable fee to the general practitioner who acts in consultation in expert called in under the Puerperal Fever Regulations, and

- (3) That it be an instruction to the Council to take all possible steps to secure that these resolutions be made a reality.

Mr E. W. G. MASTERMAN moved as an amendment that paragraphs (1) and (3) be omitted. Paragraph (1) he said, was not really the work of St Pancras. It was the result of a subcommittee appointed by the Metropolitan Counties Branch. The medical officers of health for London had requested guidance from the Metropolitan Counties Branch with regard to what fee they were to ask from the local authorities for the proffered consultant advice to be given in the case of poor people who were unable to pay, and a committee had been appointed which had put forward what was included in paragraph (1), which was a minimum fee, and a fee which did not include any operative work, and mileage had to be added. That put him back to the Metropolitan Counties Branch, and would have come forward to the Representative Meeting, but unfortunately at the time of its birth there had been annexed to it a very grotesque tail, which appeared in paragraphs (2) and (3). For that reason paragraph (1) could not come to the meeting, as it would have done from the Medical Political Committee itself, with the recommendation of the Council. He desired to move that paragraphs (2) and (3) be omitted for the reason that it was asking the Ministry of Health to pay fees in addition to giving a privilege to medical officers who were paid by local authorities to attend certain poor persons. They were giving a great privilege and opportunity to the medical man. There were not cases where, happily, many practitioners would have gained experience. There were cases where it was of the utmost importance that a decision should be come to with the least possible delay. The cases had to be notified, and immediate treatment, if it was a genuine case of puerperal fever, was necessary. They were cases where friends were very apt to make it extremely difficult for the medical man if the patients were not rightly treated from the first. They were cases where, if the medical man did not receive expert advice, he might have very disagreeable experiences, and fatal results occur. Genuine cases would, for the most part, be sent into a hospital. In short, it was a privilege paid for by the local authority, and to ask that the medical man, who was already paid for doing the work, should get another fee for having this gratuitous help, was unreasonable. At any rate the local authorities would think it unreasonable, and to put such a thing forward would be very bad policy. If paragraph (2) fell to the ground, paragraph (3) was better left out. They did not wish directly to tell the local authorities of the decision, but they left it with the medical officer of health to make their negotiations, unhampered by any opinion coming from the Association. He therefore moved the omission of paragraphs (2) and (3).

Dr D. ROBERTS (Manchester) expressed the hope that the amendment would not be adopted.

Dr BOVE supported the amendment. He considered that the original motion was the most unreasonable that had been put before the Representative Body in his time. When it was suggested that there should be consultation regarding the notification of puerperal pyrexia a conference took place on the matter, and at that conference the representatives of the profession agreed to accept notification of puerperal pyrexia on certain conditions. One of the conditions was that something should be done to help medical men in regard to puerperal pyrexia, and that they should have consultants provided, and that if necessary, the cases should be treated in institutions which were to be provided by the authorities. That condition was agreed to. But now that the consultants had been provided it was proposed that the medical man was getting the help of the consultant should if he could. He hoped that the two clauses would be omitted.

Dr C. O. HARRISON (Marylebone) said that he was present when the question was discussed by the Metropolitan Counties Branch. He asked to see the attitude which had been taken up by Dr B. I.

position, he took it, was as follows. A general practitioner in attendance on a case of confinement thought that his patient would be helped if he could have the advantage of a discussion with a practitioner specially experienced in the subject. Upon application he could get a second opinion without any charge either to himself or to his patient. It was in the interest of his patient that that course should be adopted. He had a perfect right to the payment of a fee by the patient in whose interests he was acting, but to ask the local authority also to pay a fee was surely to prefer a demand which was altogether unreasonable. It had been said that no harm could come from asking for the fee, because if the worst the request would be refused, but that was quite a mistaken position to take up. The British Medical Association was constantly in negotiation with Government departments, and it was of the utmost importance to its prestige and credit and influence that it should not advance any demand which the Government might consider unreasonable and improper. It put forward the demand now suggested it would prejudice its whole position as a negotiating body, not only on the present occasion but on all future occasions.

Dr I. W. JOHNSON considered that in asking for extra remuneration for a consultation the general practitioner was only asking for what was his just due.

Mr MASTERSMAN emphasized the fact that those concerned were primarily poor people who could not pay fees, and that the medical man engaged was approaching the local authority to give him a free consultation because his patient could not pay for it. If a patient were able to pay the fee the medical man would call in his own consultant and arrange his own terms. A somewhat parallel matter was that of small pox. If a doctor had a doubtful case he could get the Ministry of Health to send someone down to consult, but he had never heard of anyone supposing that he could demand from the Ministry a fee for having had the advice that was given.

The amendment for the omission of paragraphs (ii) and (iii) was carried by a very large majority.

The CHAIRMAN pointed out that the motion now before the meeting was the first section of the resolution.

Dr BOVE opposed the proposal. He said that if the Metropolitan Counties Branch Council desired to set up the suggested minimum fee for the members of its own Branch it was perfectly at liberty to do so, but he hoped the meeting would reject it as applicable to the whole country and would accept the suggestion of the Council that the matter should be left in a fluid condition.

Mr BURNOR HARMAN proposed, and it was agreed, that the meeting should proceed to the next business.

Dr R. G. GORDON (Bath) moved

That it is desirable owing to the fact that puerperal pyrexia may be due to causes other than obstetric that the panel of consultants to be instituted under the Regulations should include competent physicians, surgeons and pathologists in addition to consulting obstetricians, further that some standard of competence should be adopted such as membership of the staff of a local general or obstetric hospital or the possession of special qualifications or experience.

Dr BOVE, as a point of order, asked whether it was a fact that the panel of consultants was to be instituted under the Regulations.

The CHAIRMAN said that there were authorities who had instituted a panel of consultants, but to make the motion strictly in order it should be altered so as to read "that the panel of consultants which may be instituted."

Dr GORDON said that according to the definition of puerperal pyrexia a temperature of over 100° F was accepted as such. It was felt by the Bath Division that such a temperature might mean that the patient was not only suffering from some condition which came under the purview of the obstetric specialist, but from pneumonia or any other general medical or surgical illness, and that therefore it was fair to the general practitioner to allow him to call in consultants other than obstetricians. The suggestion had been placed before the Ministry of Health, but the Ministry had replied that the panel should consist of obstetricians only. It had been suggested to him that the motion would be improved by the insertion of the words "general practitioners possessing special qualifications," so that it would not be implied that the panel of consultants

need necessarily consist of a whole-time specialists. He was certain that the Bath Division would agree to the modification if it was the wish of the meeting.

Dr R. BOYD (Manchester) supported the motion, especially the last clause of it which seemed to him to be the most important. The general practitioner was credited with being the greatest sinner in many cases of puerperal pyrexia. If that was so he ought to have the greatest knowledge as to how to treat the cases. Equally the gynaecological consultant ought to have very little knowledge of such cases, especially as the patients were removed from the hospital immediately they became cases of puerperal pyrexia. The speaker concluded by requesting a ruling from the Chairman as to whether the words "competent physicians, surgeons" included general practitioners.

The CHAIRMAN replied that it was not his business to interpret motions.

Dr BOYD then moved as an amendment that the words "physicians, surgeons" should be deleted and the word "practitioners" inserted in their place.

Dr W. T. DEMPSEY seconded this amendment. There seemed to be some doubt as to the definition of a practitioner. He had always understood that a medical practitioner was one who practised all branches of medicine and surgery. It was a very convenient term because of its wideness. "Physicians and surgeons" was not so wide a term; it was subject, probably, to several interpretations and might lead to complications in defining the resolution if it was ultimately passed.

The amendment was lost.

Dr GORDON thought that the difficulty might be cleared up by altering the last clause to read "or by private practitioners possessing special qualifications and experience."

The CHAIRMAN said that it was certainly desirable to make it clear in this motion that general practitioners were not excluded.

Leave was given for the motion to be amended in this sense, and the motion was then adopted.

#### Workmen's Compensation

Dr R. P. GARRON (Chesterfield) moved to express the strong opposition of the Association to the practice of some inspectors, not being medical men acting on behalf of employers' liability insurance companies of requiring or suggesting the removal of properly applied dressings when visiting injured workpeople in order that they may see the injury, and to instruct the Council to enter a vigorous protest.

Dr BOVE suggested that the Council should be asked to consider the matter. He had no personal knowledge that the kind of thing alleged was done to any considerable extent, and it was a matter which should be investigated before entering upon any protest.

Dr GARRON concurred with this suggestion and in that form, as a reference to Council the motion was carried.

#### Remuneration of Assistant in General Practice

Dr J. S. MUIR (Selkirk) moved to substitute the following for the opening sentence of a resolution passed by the Representative Body in 1925 regarding the remuneration of assistants:

That in view of the fact that an assistantship is commonly to a young practitioner a continuation of his medical education and training the value of which is variable and impossible to estimate, no definite figure can in these circumstances be fixed as a minimum salary, but in cases where the above consideration does not prevail and where the practices can afford it the minimum commencing salary for a whole-time indoor assistant to a practitioner should be £240 per annum etc (as set out in the 1925 resolution).

The 1925 resolution had it down that the minimum commencing salary should be £240, with the addition of board and lodging, the value of the board and lodging to be estimated at from £120 to £160 per annum, according to the circumstances of the case when such a practitioner was employed on an outdoor basis. Dr MUIR said that he spoke for a Division (the Southern Counties, Edinburgh), and in passing the resolution of 1925 his Division thought the Representative Body had failed to recognize the tremendous divergence in the financial position between rural practitioners and those in urban and thickly populated

districts. If this resolution was persisted in it would become a practical impossibility for many men in his Division to obtain assistants at all. He read a letter from a fellow country practitioner, who wrote "Country work is not remunerative. The country doctor works under serious disadvantages, at great expense, and for poor fees. He requires assistance even more than the town doctor, who has neighbours to help him, but he cannot afford to pay for it." When it was said that the commencing salary for the newly qualified, inexperienced practitioner should be such and such a figure, he thought it should be the other way about, and that the newly fledged man from college should rather pay the experienced principal to instruct him! In particular he had to learn, what few of them knew at first, a good bedside manner.

Dr BONE hoped the meeting would not tamper with the policy adopted two years ago in this direction. It was not a compulsory policy, but merely tentative, for the guidance of the office. The Council, by putting a paragraph on the subject in the annual report, had signified its wish that this should be discussed by the Representative Meeting. The Council was not convinced that the moment had come to strengthen the policy, as a subsequent amendment urged, but it was sure that this was not the time to go back on the policy.

Dr Muir's amendment was lost.

Dr W. A. M. SWAN (St Pancras) moved to rescind the following part of the same resolution of the Representative Meeting, 1925:

That no steps should be taken for the present to make the foregoing expressions of opinion the policy of the Association, but they should be used for the assistance of the office in advising on points connected with the terms and conditions of the work of assistants. While an advertisement is offered for insertion in the *British Medical Journal* in connexion with an assistantship not in accordance with the foregoing opinions, the attention of the advertiser should be drawn to them in the hope that the advertisement will be amended, but the advertisement should not, if otherwise eligible, be refused.

He moved this from the opposite point of view to that of the mover of the last amendment—namely, that the policy should be strengthened.

The CHAIRMAN (Dr Brackenbury) said that the Council had wished to get from the Representative Body some guidance with regard to this matter. It had felt that an opinion as to the proper remuneration of an assistant to a general practitioner could better be obtained from the Representative Body than from any other source, therefore it did not itself make any addition to the recommendations made two years ago, but it hoped to receive enlightenment at that meeting.

The MEDICAL SECRETARY said that the difficulty at headquarters was that, although the Representative Meeting seemed enthusiastically in favour of a standard of remuneration for assistants, yet advertisements from members of the Association were constantly being received in which an endeavour was made to get assistants for less than the sum stated, and not only so, but there were young qualified men and women who were ready to do the work for less. What he wanted to know was whether this policy of a minimum salary for assistants was getting stabilized.

Dr BONE said that they were always being twitted with setting up scales of remuneration, especially for whole-time officers, while leaving their own assistants unprovided in this respect. The matter should be left as it was. The economic position in the medical profession to day was a little worse, and not better, than it was when the scale was passed. He believed that there were more unemployed in the profession at the present time, particularly among women, than was the case two years ago.

Dr SWAN withdrew the amendment.

#### Coroners (Amendment) Act

Dr J. G. MACQUEEN (Hyde, Stockport, etc.) drew attention to the position of the doctor reporting a death to the coroner, the coroner asking for a report, and calling upon someone else to make the post-mortem examination. The report of the doctor did not receive a fee, and Dr Macqueen moved that a fee should be paid for a report in the case

of a practitioner who did not perform the necropsy and was not called to give evidence.

Dr BONE said that this point was pressed at the time the Coroners (Amendment) Bill was before Parliament. It was not secured, and there would be no opportunity of securing anything of that kind for probably half a century. The only remedy was to refuse to give a report or to agitate locally for payment for such reports which in some areas were paid for. Nothing could be done centrally.

The CHAIRMAN said that the motion expressed what was the policy of the Association, and there could be no objection to it being reiterated.

#### Medical Certification of the Blind

Dr E. I. CLAYTON (Liverpool) asked that representations should be made to the Ministry of Health to secure that medical certification should be required for all entrants in any grant-aided service for the blind, and that for such certificates there should be a uniform fee. He said that the responsibility of furnishing certificates for the blind rested with the local authority. In some cases the local authority stood down, and the ophthalmic surgeons were asked to furnish these certificates by charitable societies, who sent these cases to the eye hospitals.

Mr BISNOR HARMON asked that this might be referred to the Council for consideration and report. He pointed out certain difficulties, and said that it would be unsafe for the Representative Body to pass a mandatory resolution on a subject which clearly called for further investigation.

This course was agreed to.

#### Nursing Homes Bill

Sir RICHARD LUCE, M.P., made a statement on the Nursing Homes (Registration) Bill. The Select Committee, after the evidence it received, could not agree that it was advisable for doctors to be exempted in respect to their premises used as a nursing home. The Council had now come to the same conclusion, and in the bill at present before Parliament no steps were being taken to provide for any special exemption of medical men who were owners or administrators of nursing homes. An important matter was now before Parliament. The bill as it stood laid it down that the registering authority should be either the county or county borough council. There was a strong movement in Parliament from a certain section to get that authority very much widened and to make it include any body having control over maternity welfare. This would throw it open to very much smaller bodies than county or county borough councils. Those who spoke for the profession maintained that it was essential that the inspecting officer should be a person of the status of medical officer of health for the county or county borough. An amendment was being put down to ensure, if possible, that the inspection should be kept at the higher standard. The amendment, as it stood at present, was to the effect that the man who had access to these homes should be the medical officer of health of a county or county borough or such of his assistants as might be duly authorized by him. The medical men in Parliament would do their best to see that the position was safeguarded.

#### OVERSEA BRANCHES

The discussion on the report under "Medico-Political" was interrupted, after lunch on Monday, to permit of the business under "Overseas Branches" being taken, as decided on Friday when considering the agenda.

Sir JENNER VERRALL, Chairman of the Dominions Committee, moved approval of this part of the Annual Report of Council. He said the parts of the world they had had to deal with were very much the same as on other occasions. On the whole, the things they had tried to effect had been successful. For instance, in the East African Medical Service there certainly were improvements. The only dubious point was the position of the man entering the service, which was not quite as certain good as that of the man already in. That made it more difficult to recommend a man to go into the service. The future was uncertain, they had applied for information which the department had not been able to supply, they would keep their eyes open and act accordingly. In Malaya,

also there had been an improvement, though a unification of the service was at present impossible, quite as much for political as for medical reasons. In the Windward Islands the conditions were nothing like satisfactory. The ordinances to which the Association objected had not been repealed hence there remained in force the "Important Notice" to people who thought of entering the service that they should apply to the Association for information as to the probable conditions under which they would have to work. The bill to regulate medical education in India was practically dead and not likely to give more trouble. In Hong Kong there was an improvement in the conditions of medical practice in regard to fees paid by patients in Government hospitals. Sir Jenner Veirall added that the old poisonous still needed attention, and they would do their best to deal with any further needs that arose. He echoed in imitation previous by given by the Chairman to over his officials and members of the Association to give the Representative Body the benefit of their experience and advice. The Australian Branches afforded a splendid example of the working of the Association. They were doing good work and maintained a high percentage of the "valuable practitioners" within them. With regard to South Africa they understood list item that the visit of Dr Cox had placed things on a satisfactory footing and they were not disappointed in that respect. He invited representatives from South Africa to tell the meeting distinctly and boldly how the arrangements then made were working. He believed they would make for peace and progress.

Mr T LINDSAY SINDES (Cape Western) officially presented the thanks of his Branch and of the South African Federal Council of which he was Vice-President, for all that the British Medical Association had done in helping to place the organization in South Africa on a much more satisfactory basis. There was now only one medical organization in the Union—the Medical Association of South Africa (British Medical Association) (Applause). He doubted if the efforts that had been made to co-ordinate societies would have succeeded but for the visit of Dr Cox who by his marvellous abilities and intuition brought the matter to a successful termination (Applause). The first Medical Congress under the new regime would meet in March, 1928. When in the United States recently he heard that there was a possibility of some American surgeons visiting South Africa so he personally invited the President of the American College of Surgeons in Chicago to attend the Congress and he had since heard that 200 people had chartered a special boat and would pay them a visit. Later he went to Holland which had close racial association with a large proportion of the population in South Africa and invited some of the leading practitioners there to visit South Africa. He extended the same invitation to members of the Representative Body. A visitor from overseas was struck by the number of Englishmen who spent all their holidays wandering about Europe. He suggested that they should spend a little extra time in going further south and seeing some of their own overseas Dominions. ("Hear hear.") A two months' holiday would give them four weeks in which to see the Union. There was a strong desire that the President of the British Medical Association should attend the March Congress. Although co-ordination of the profession in South Africa had taken place difficulties remained that would require careful attention for years to come. The Empire now was held together by sympathy and affection, and personal contact did far more than volumes of correspondence. (Applause.)

Dr J L REIDICE (Cape Midland) endorsed what Dr Sinde had said, and emphasized the points he had raised. The young Association in South Africa was making wonderful progress. At Dr Cox's suggestion they had formed divisions, because of the distances between outlying stations were so great as to make attendance at meetings difficult. By splitting up into smaller Branches they could keep in contact with one another and discuss medical and other subjects more mutually and make the Association a real thing. Dr Cox did wonderful work. He went not merely to the towns and centres, but to the little dorps—country villages almost—to farms and hamlets getting into personal touch with people, and as a result there was a considerable accession to the membership of the Association. Unfor-

tunately there were still difficulties, and he urged the Representative Body to persuade the President of the British Medical Association to visit South Africa and attend the Congress.

Dr A GOW (Pretoria) remarked that the Branch in South Africa had its local difficulties, which required the greatest sympathy and support from the parent body and he desired heartily to support the plea that the President should attend the forthcoming Congress to be held in Bloemfontein. He wished also to pay a high tribute to the fine work done by Dr Cox in bringing together the profession in South Africa and in securing a cohesion of medical policy there. As an instance of this he mentioned that whereas prior to the visit of Dr Cox the Pretoria Branch had consisted of 60 members, it now had 110. (Applause.)

Dr L D PAINSON (Ceylon) said that he desired to thank on behalf of his Branch all those in the Association who had so much interested themselves in and had assisted those who practised in Ceylon. He mentioned that an attempt had been made in India to pass a bill to register native practitioners of medicine. That bill had been dropped but in Ceylon a very determined effort had been made by a large number of influential natives many of them members of the Legislative Council to get a similar bill passed in Ceylon and to ask the Government to spend a large sum of money in educating those people in what was termed indigenous medicine. The local Branch had taken a very keen interest in the matter as a result of which the secretary had gone to Madras, Bombay and Calcutta, and had made a special report to the Branch. Personally he had no doubt that the central Council in London would very carefully watch the interests of practitioners in Ceylon in the matter. It was not only their own interests they were thinking of but of His Majesty's subjects in Ceylon. There were quite enough practitioners in Ceylon to provide modern medical treatment for the people there. There were from 500 to 600 hospitals and dispensaries in Ceylon for a population of five million people.
